COBRA 2011
Proceedings of
**RICS Construction and Property
Conference**

12-13 September 2011
School of the Built Environment
University of Salford

Editors: Prof Les Ruddock; Dr Paul Chynoweth
ISBN: 978-1-907842-19-1

PREFACE

Dear Conference Participants

It gives me great pleasure to welcome you to COBRA 2011 - the Royal Institution of Chartered Surveyors International Research Conference - hosted by the University of Salford.

When Cobra was first held in 1995, its aim was to be a fully refereed conference targeted at those whose research fell into the broad scope of the Quantity Surveying and Building Surveying Divisions of the RICS. Since then the scope has expanded to cover research associated with most of the Professional Groups within the RICS.

The Conference was formed to encourage synergy between the professional and academic sectors of the construction and property industries and to act as a forum for the dissemination of this activity. The papers in the conference proceedings of this, the Seventeenth COBRA Conference, show how well this objective has been achieved.

COBRA is a high level research conference:

- Presenting the best of construction, building and real estate research worldwide
- Stimulating debate and discussion between researchers from around the world
- Providing the basis for new areas of research

The Editors are indebted to the members of the Review Committee, who reviewed the papers and whose comments assisted authors in the development of their papers.

All the papers accepted for the Conference Proceedings were selected on the basis of double-blind peer review by the scientific committee members and paper reviewers to ensure a good quality standard. I hope that delegates will obtain useful feedback to their ideas, gain insights from the work of others and forge connections that will endure.

Finally, I express my gratitude to those individuals, who played an important role in the organisation of COBRA 2011. In any endeavour of this sort, there are a few individuals who are absolutely crucial to ensuring the successful running of a conference.

The Theme Leaders (Dr. Paul Chynoweth, Prof. Charles Egbu, Dr. Monty Sutrisna and Prof. Ali Parsa) and the University of Salford Conference team (Clare Forster, Vicky Beckett and Daniel Fenby) must be mentioned. Dr. Kaushal Keraminiyage performed the essential tasks of building and supporting the web pages and the paper reviewing system. But particularly special thanks must go to Mrs. Karen West for her never-ending work in managing the papers (and their authors) in a tireless yet astonishingly cheerful manner!

Prof. Les Ruddock
Conference Chair

KEYNOTE PRESENTATIONS

Clients want performance!

Prof. Ger Maas

Ger holds the posts of Director of Strategy at Royal BAM Group and is also Professor of Construction Management at the School of Architecture, Eindhoven University of Technology.

He is currently the President of ENCORDER (European network of large construction companies for R&D) (www.encorder.org) and the Chairman of the High Level Group of the European Construction Technology Platform (ECTP).

Ger's presentation will refer to his work for ECTP and ENCORDER and the different subjects or developments that are on the agenda at European level.

The changing nature of real estate as an investment asset and the implications for property professionals.

Prof. Paul McNamara

Paul is responsible for the overall direction of property research within PRUPIM, a top twenty global real estate fund manager, where he heads up the Global Property Research Team.

A Visiting Professor at Oxford Brookes University, he is also a former Chairman of the Investment Property Forum and Chairman of its Research Steering Group. Paul was awarded the OBE for services to the property industry in 2003 and received a lifetime achievement award by IPE in 2008.

REVIEW COMMITTEE

All papers submitted to COBRA 2011 were subjected to a double-blind (peer review) refereeing process. Referees were drawn from an expert panel, representing respected academics from the built environment research community. The conference organisers wish to extend their appreciation to the following members of the panel for their work, which is invaluable to the success of COBRA.

Prof. Carl Abbott, University of Salford, UK
Prof. Paul Bowen, Cape Town University, South Africa
Dr. Paul Chynoweth, University of Salford, UK
Prof. Charles Egbu, University of Salford, UK
Dr. Louis Gunnigan, Dublin Institute of Technology, Ireland
Prof. David Jenkins, University of Glamorgan, UK
Prof. Keith Jones, University of Greenwich, UK
Prof. Jorge Lopes, Polytechnic Institute of Braganca, Portugal
Dr. Kathy Mitchell, Cape Town University, South Africa
Dr. Henry Odeyinka, University of Ulster, UK
Dr. Ali Parsa, University of Salford, UK
Dr. Steven Ruddock, University of Salford, UK
Prof. John Smallwood, Nelson Mandela Metropolitan University, South Africa
Dr. Robby Soetanto, Coventry University, UK
Dr. Monty Sutrisna, University of Salford, UK
Dr. Will Swan, University of Salford, UK

LOCAL ORGANISING COMMITTEE

Alternative Dispute Resolution

Utilizing ADR to resolve Construction Disputes: A quantitative survey of Scottish legal practitioners' awareness and experiences

Andrew Agapiou¹

¹Department of Architecture,
University of Strathclyde, Glasgow, G4 0NG,
United Kingdom

Email: andrew.agapiou@strath.ac.uk

Abstract:

It is widely documented that legal practitioners perform a gate-keeping role, advising clients on the most appropriate form of dispute resolution for particular cases (Agapiou & Clark, 2010). It would be interesting to ask whether the attitudes of the legal fraternity in Scotland creates a real limit on what could be implemented by a government that seeks to promote novel means of dispute disposal as part of its civil justice reform agenda. Drawn from questionnaire - based research, the aim of this paper is to establish lawyers' awareness, attitudes and experiences of Alternative Dispute Resolution (ADR). Despite the small sample used in this study, there is evidence that more education in ADR procedures and their application could provide further opportunity to develop them as settlement tools in Scotland by building on more positive aspects of responses within the survey. Only some in the legal fraternity have embraced the challenge of what the study has found to be regarded widely as an opportunity. Further education, training and publication of successful execution may be necessary to convince doubters that ADR needs to be part of the menu of methods of dispute resolution for the modern practitioner.

Keywords:

alternative dispute resolution, lawyers, Scotland

1 Introduction

There is no doubt that ADR has experienced growth over recent years. The Eversheds' survey found 41% of litigants had used ADR in 2000, compared to 30% in 1998. However, it has been concluded 'that over 96% of the respondents in a 1997 survey by Brooker and Lavers had never used any form of ADR (Brooker and Lavers, 1998). 70% of those respondents who have never used ADR said they would consider doing so, although a surprisingly large proportion (27%) said they did not know...Only 3% (6 of the 229 respondents) said they would not use ADR'(Gould et al, 1998). By 2001, it would seem that matters had moved forward in respect to the use of mediation. In a postal survey, Brooker and Lavers (Lavers and Brooker, 2001) reported that 66% of respondents had used mediatory techniques to resolve disputes. Similarly, in a 2010 survey of

construction lawyers in Scotland, 58% of respondents had working experience of representing a party in at least one mediation case (Agapiou & Clark, 2010). The government has also influenced growth over time. For example in March 2001, the Lord Chancellor pledged that standard government procurement contracts would incorporate clauses to promote the use of ADR to resolve disputes as an alternative to litigation. By 2008, the figure had increased to 314 referrals (Lynch, 2010). Despite the fact that much has been written about lawyers' role in and experiences of ADR in commercial disputes in Scotland, and construction matters in other jurisdictions such as England and Wales and the USA (see for example, Povey (2005)), little is known about lawyers' interaction with the process with regard to disputes in Scotland. While recent research has focused on Scots construction lawyers' experience of and attitudes to mediation in construction disputes (Agapiou & Clark (2010), the research presented in this paper covers a wider and more in-depth investigation of lawyers' opinions encompassing early neutral evaluation, conciliation and min-trials. This paper seeks to establish the level of awareness of, interest in and concerns regarding Alternative Dispute Resolution among Scottish legal practitioners, and to assess the implications for the resolution of disputes within the construction industry.

2 The growth of ADR in Scotland

Seemingly, the Commercial Court in Scotland does not have the power to direct the use of ADR without the consent of the parties. The enthusiasm of the English courts for the use of ADR to resolve disputes was driven by the Woolf Review, and the subsequent introduction of the Civil Procedure Rules (Gould, 2009). The ability in the English Rules to encourage the use of ADR has been backed up by comment and orders from judges in a series of cases since 2000 culminating in the decision of the Court of Appeal in *Halsey v Milton Keynes NHS Trust* decided in May 2004. Further examples where the English courts would not tolerate the unreasonable refusal to take part in mediation where the parties have contracted to mediate or where the courts consider it might achieve a settlement outcome include *Burchell v Balland* in April 2005, *Wethered Estate Limited v Michael Davis and Others*, and *Earl of Malmesbury v Strutt & Parker* decided in March 2008. Nonetheless, it is difficult to trace similar judicial enthusiasm in Scotland, according to Clark (2008). There does not seem to be an equivalent rule in Scotland that encourages the use of ADR in either the Court of Session rules or the Sheriff Court rules. The only exceptions to that are contained in the rules for conduct of Commercial Actions in the Court of Session introduced in, December 2004, and the rules for Commercial Actions in the Sheriff Court which were introduced in March 2001. Although these rules have been introduced there is little evidence of the use of ADR being encouraged to resolve commercial disputes either by Court of Session judges or by Sheriffs. Nevertheless, pilot schemes involving in-court mediations were established by the Scottish Government in Sheriff Courts across Scotland. These were designed to test different models of provision to help inform discussions about future sustainability of mediation services. However, according to Clark (2008) these were confined to low value claims involving individuals rather than commercial disputes. Many commentators (e.g. Clark, 2009) have suggested that there is little demand for ADR in Scotland, citing judicial attitudes; change resistant legal profession;

absence of an ADR body and lack of client awareness, as barriers to the further development of ADR within the Scottish arena.

2.1 Legal Profession

In most cases, when clients bring their disputes seeking advice, lawyers automatically enter into litigation: the adversarial process they are familiar and comfortable with, without any thought to possible alternatives. Not only is ADR an 'unknown quantity' to many in the legal fraternity, they also appear unwilling to view it as an opportunity to expand their dispute resolution business rather than a threat to their fee income. This is true notwithstanding the fact that 94% of court actions generally settle (30% of these within one week of proof) (Brooker and Lavers, 1998). Surely the Scottish legal profession should be more enthusiastic in their promotion of alternatives to avoid such 'door of the court settlements', if for no other reason than to attain reduced client costs? There was some interesting research on this matter conducted by Agapiou & Clark (2010). The authors surveyed Scottish construction lawyers and, amongst a series of interesting results, found that almost three-fifths of respondents (58%) had working experience of representing clients in mediations; with 57% citing reduced client costs as by far the most important determining factor in recommending mediation to a client.

2.2 ADR Body

Prior to the establishment of Core Mediation in Edinburgh there was no accreditation body with the necessary infrastructure to supply appropriate mediators and manage disputes from initial enquiry through to a concluded mediation. Whether the existence of such a body will allay any fear judges may have regarding responsibility for the conduct of mediation cases before the courts remains to be seen. In a response to the Scottish Civil Courts Review Consultation Paper, Core Mediation highlighted that they had conducted over 200 mediations since 2002 (Sturrock, 2007). Although this may seem a small number on face value, it is interesting to note that of the total mediation many have taken place within the last few years.

2.3 Client Awareness

With ADR being little used in Scotland and lawyers reluctant to promote it, commercial clients are on the whole unaware of its possible benefits which have led to a resultant lack of demand. However, many large commercial disputes in Scotland involve international companies. Perhaps the greater use of ADR in other jurisdictions may well lead to a better appreciation of its benefits within the Scottish construction context, resulting in similar growth in Scotland as has been seen in England. Ultimately, such demand may force Scottish legal practitioners to expand their dispute resolution portfolio, or risk losing their clients' base (Clark, 2008).

2.4 Prospect for change in Scotland?

Scotland has not been as radical in its reforms of the civil justice system. In spite of calls and measures to encourage ADR, including the introduction in 2001 and 2004, respectively, of rules governing Commercial Actions in the Court of Session and to rules for Commercial Actions in the Sheriff Court, there is little evidence to suggest that ADR has been widely embraced north of the border

(Clark, 2009). Indeed, is there any prospect that ADR will ever gain credibility and acceptability amongst the judiciary, legal professionals, clients and government in Scotland? Interestingly, there has been plethora of government reviews and consultations focusing on reform of the civil justice system in Scotland since 2001, cumulating in the publication of the Gill Review of Civil Justice in 2009. All the reports are, to a certain extent, critical of the status quo and have been instrumental in moving the ADR agenda forward by advocating a move away from litigation towards more consensual approaches to dispute resolution, particularly from a value for money and access to justice perspectives (see for example, Scottish Consumer Council (Civil Justice Advisory Group), 2002). In 2007 the then Scottish Executive [now Scottish Government] published a report entitled 'Modern Laws for a Modern Scotland – A Report on Civil Justice in Scotland'. The report itself was a response to the Scottish Consumer Council's call for a review of the Civil Justice System in Scotland. It compares and contrasts the range of dispute resolution options available to disputing parties, but rather than describing them as either consensual or binding methods, the authors of the report suggested that options should be viewed as being on a continuum ranging from least [court] intervention at one end to most at the other. The Scottish Executive report seems to endorse the Sheriff Court Rules Council and the Court of Session Rules Council governing the use of ADR in the court process, while suggesting that ADR, and especially mediation, should be an integral part of civil justice system in Scotland following Lord Gill's Review (Gill, 2009). Nevertheless, it seems unlikely that the proposals in the Gill Review will lead to a rapid adoption of ADR in Scotland, as compared to the proposals within Woolf Review within England and Wales. Notwithstanding the recommendations of the Gill review, the power to make an order for ADR to take place already exists in the Sheriff Court rules, so can we presume that this power will begin to be used in appropriate cases?

3 Data Collection & Analysis

The aim of the research was to establish the level of awareness of, interest in and concerns regarding ADR relative to legal practitioners in Scotland. Having defined the framework for the survey, the next step was to develop the necessary data collection tool in accordance with the research objectives. The questionnaire was distributed via the internet to 600 legal professionals randomly selected from the membership lists of professional associations for Solicitors & Advocates (Advocates are Barristers in Scotland) based and operating in Scotland.

3.1 Data collection process

Since the questionnaire was self-administered, there was a need for it to be self-explanatory. In order to achieve this, a covering letter and an introductory page describing the aims and objectives of the research was attached to the questionnaire. The questionnaire was structured into 3 sections: Firstly, a number of variables from the survey were selected from the questionnaires as the basis for assessing the use of ADR including the background and experience among Solicitors and Advocates, their training in ADR and organisational policies and practices towards ADR. Secondly, in terms of experiences of ADR, respondents were asked to rate the extent of their and their firms' involvement within civil disputes cases over the last 12 months as well as the extent to which ADR

procedures were actively used to resolve these disputes. Thirdly, as part of the study the respondents were asked to rate their perceptions of dispute resolution and ADR. The purpose of the questions was to ascertain an understanding of the barriers to the use of ADR more generally and for construction disputes in particular. The attitudes were measured by asking the sample frame to rate their responses to 11 statements on a Likert scale (strongly agree =1; moderately agree = 2; neither agree nor disagree = 3; moderately disagree = 4; strongly disagree =5).

3.2 Survey Results

A total of 600 questionnaires were distributed among legal practitioners in Scotland. Of the total, 191 were returned by post wholly or substantially completed, which represents a response rate of 32%. According to Andrews et al (2002), this a relatively high response rate for web-based surveys. McAdoo et al (2003) concur that a 32% response rate is relatively high for and social science-based surveys of legal practitioners.

1.1.1 Background of the respondents and their organisations

A number of variables from the survey were selected from the questionnaires as the basis for assessing the knowledge and use of ADR including the background and experience of the respondents in the legal profession, their training in ADR and organisational policies and practices towards ADR. Of the total numbers of practitioners who responded, 57 % described themselves as Partners, 20 % as Associates, 15% as Advocates and the remainder as QCs and Assistants. In terms of numbers of years within the legal profession, almost 80% of respondents had practised law for more than 10 years, with 20% having more than 30 years' experience in practice.

1.1.2 ADR training

A number of questions focused on formative training in ADR methods among legal practitioners at pre and post qualification stages. In terms of whether respondents had training in consensual forms of dispute resolution prior to entering legal practice, the figures were consistent among legal practitioners. It seems that 95% of those who responded had not received training in ADR techniques. Perhaps this is a reflection of the relatively novelty of ADR as a dispute resolution mechanism within Scotland per se and the lack of taught provision within the respective Law Schools more specifically? However, this finding is consistent with to Clark & Dawson's 2007 survey in which only 4% of respondents had any exposure to mediation at Law School (Clark & Dawson, 2007). It seems that training in ADR techniques increased after respondents had entered legal practice. Around 22% of respondents had received some formal training in ADR techniques. It is widely recognised that post-qualification training had undergone significant reform in recent years. The reforms developed and introduced through organisations such as Core Mediation & the Scottish Mediation Network have been instrumental in promoting more consensual forms of dispute resolution in Scotland such as mediation among newer members of the profession, especially (Sturrock, 2007).

Client representation in Civil Disputes

The questions asked respondents to indicate their and their firms' involvement in civil dispute work over the previous 12 month period. It seems that civil dispute work comprised in excess of 50% of the total workload of 42 % of the practitioners who responded to the survey (see Table 1). However, it seems that only 17 % of their firms had a workload in which civil dispute work comprised more than 50% of overall activity. Thus, it would appear that 83% of practitioners who responded worked in firms whose civil dispute work comprised less than 50% of their firm's workload (See Table 1).

Table 1. Client Representation in Civil Disputes

Percentage of time representing client in civil disputes	Individual practitioner' Response %	Respondents' Firm Involvement %
None	15	11
Less than 25%	29	42
Between 25% and 50%	13	30
Between 50% and 75%	12	8
Between 75% and 100%	31	9

1.1.3 Methods of dispute resolution employed

The question sought to ascertain the methods of dispute resolution employed by legal practitioners in Scotland. It was in three parts on each of the surveys. Firstly, it dealt with legal practitioners generally in Scotland in part (a), then focused on the respondent's firm in part (b) and then the firm in the last year in part (c).

Litigation, Negotiation & Arbitration

It seems that litigation and negotiation were almost universally recognised as means of dispute disposal employed regularly by practitioners in Scotland. It would appear from the survey that Arbitration received wide support as a means of resolving disputes although it was noteworthy that of 109 lawyers who identified it as a method of dispute resolution only 36 had actually used it within the last 12 months. These figures seem to reflect a decline in the overall use of Arbitration more generally (Kennedy et al, 2010), and are consistent with several studies on the Arbitration in Scotland, specifically (Dundas and Bartos, 2010).

Adjudication, Mediation and Conciliation

Around two-thirds of the total respondents recognised Adjudication as a means of dispute resolution employed by legal practitioners in Scotland. Nevertheless, it seems that only 8% of those who responded to the survey were actively involved with the process. These figures may reflect the increasing involvement of other professionals in adjudication procedures, and are consistent with the findings of the recent studies of the Adjudication process (Kennedy et al, 2010). The respondents also seem to have recognised Mediation as a means of dispute resolution involving legal practitioners with responses almost mirroring the support for Arbitration. Around 57% of the total number of those who responded

to the survey recognised Mediation as an ADR process employed by Scots legal practitioners. As will be seen later in the survey, these figures perhaps reflect the fact that mediation is viewed as a prominent method of dispute resolution in Family, Matrimonial and Employment matters (Lynch, 2010). These are both specialist areas and they would therefore have many fewer practitioners active in them. Around two-thirds of lawyers who responded recognised conciliation as a method of dispute resolution in Scotland (see Table 2). However, the level of active involvement is much less in this case with 21% of respondents actively involved in the procedure. While conciliation is a term used particularly in the area covered by Tribunals, it is often used as an alternative expression for mediation and indeed the terms are often interchangeably within legal texts (Clark, 2009).

Table 2. Use of ADR

	Legal practitioners in Scotland (N)	Your Practice (N)	Your Practice within the last 12 months (N)
Litigation	112	102	100
Negotiation	113	104	101
Arbitration	109	45	36
Adjudication	79	22	21
Mediation	108	48	38
Conciliation	18	10	6
Neutral Evaluation	15	10	6
Mini Trial	5	3	3

Nevertheless, while conciliation may not have any legal standing, it differs from mediation in that parties are not required to meet as part of the process.

Neutral Evaluation & Min-trials

It seems that Neutral Evaluation was recognised by only 8% of respondents as a method of dispute disposal used in Scotland. Even fewer respondents recognised mini-trials as a means of dispute resolution in Scotland, and had been involved with it to a large extent over the last 12 months. It seems that while the procedures are being used to suit particular situations and needs in dispute disposal, their identification and use is only marginal. Unless a particular method was specified in contracts for dispute disposal as happens with arbitration and adjudication, or was the known industry method e.g. conciliation in employment disputes, then there appears to be little use of ADR to settle disputes. Most disputes appear to be resolved by either by negotiation or litigation, generally.

1.1.4 Recent experience of using ADR processes

In terms of respondents' most recent dispute experience, it seems that litigation was, overwhelmingly, the most common method for resolving disputes in Scotland according to the figures in Table 3).

Table 3. Recent experience of ADR processes**

	0	1-5	5-10	10-20	20+	50+
Litigation	16	11	4	14	68	68
Arbitration	45	49	4	4	2	1
Adjudication	60	21	4	2	4	1
Mediation	56	35	9	7	2	2
Conciliation	60	15	6	6	3	2
Neutral Evaluation	60	4	0	0	2	0
Mini-trial	65	4	0	1	0	0
other (please specify)	40	0	1	1	2	3

**The total minimum number of procedures in each category group is added up then on the basis that respondents represented clients on each side of the same dispute

The question sought to ascertain the level of use of litigation and alternative means of dispute resolution among the sample of respondents. The respondents were asked to indicate the total number of cases dealt with by type of means of disputes resolution ranging from 0-50+ for all practitioners. It would appear even on the most arbitrary level of assessment taking the response at the bottom of the range, that litigation was used on 4931 instances (see Table 3), whereas other means of dispute resolution were used on 1208 occasions: litigation accounting for over 80 % of the total number of total number of cases resolved. In fact this figure itself could be a gross underestimate of the actual number of litigations being handled by respondents as, for instance, one lawyer stated that that he had handled over 400 cases involving litigation. This certainly may be an exception but may also be indicative of much higher levels of involvement with litigation as compared to the volume of cases calculated through an arbitrary assessment of cases.

1.1.5 Appropriate use of ADR

This question proved the most challenging for most respondents. Many of the respondents made numerous entries identifying that many of the ADR procedures were appropriate means of resolution given the nature of the dispute. A few respondents made only one or two entries with still others making no entries that may suggest that none of the procedures were appropriate. There seems to be a clear consensus among the respondents that mediation was appropriate for family and matrimonial disputes. Of the lawyers who responded to the survey 94 considered mediation appropriate for family and matrimonial disputes (see Table 4).

Table 4. Appropriate use of ADR

	Arbitration	Adjudication	Mediation	Neural Evaluation	Mini-Trial	Other
Construction	70	75	51	28	12	8
Family or matrimonial	12	9	140	25	8	13
Medical negligence	22	21	42	32	11	16
Employment	45	26	35	25	12	11
Other Civil	45	29	57	22	12	13

This figure equates to 49% of the total respondents. There also seemed to be a consensus among respondents, albeit to a lesser extent, that mediation was appropriate in resolving employment-related disputes. It would seem that respondents considered binding procedures to be the most appropriate for resolving construction disputes. Indeed, around 58% of those who responded to the survey acknowledged Arbitration and Adjudication as standard methods of resolving such disputes. It was possible that some of the respondents reserved their position regarding the use of adjudication for the resolution construction disputes. The question sought means of resolution, implying permanence, and while pragmatically adjudication often was, in fact, resolution of the dispute, technically it is only temporarily binding (Dundas & Barton, 2010), and many of the respondents would be familiar with that particular paradox. There did not seem to be significant support for any particular ADR procedure for disputes involving medical negligence matters although mediation and ENE were identified as most appropriate among legal practitioners. Indeed, 5 % of those who responded identified mediation as the most appropriate means of ADR, while ENE was identified by 8% of respondents as most suitable in medical negligence cases. It would appear that Mini-trial was the procedure that seemed least understood by respondents. Many of those who responded to the survey considered all other means of ADR appropriate to many of the disputes ahead of the mini-trial process.

1.1.6 Legal practitioners' attitudes to ADR

ADR and business relationships

It seems that the majority of those who responded to the survey considered that dispute resolution avoiding judicial or quasi-judicial methods would better preserve business relationships, with 52 % of respondents in strong or moderate agreement with the proposition (see Table 5).

Table 5. Legal practitioners 'attitudes to ADR

	Strongly agree (%)	Moderately agree (%)	Neither agree nor disagree (%)	Moderately Disagree (%)	Strongly disagree (%)
Dispute resolution avoiding judicial or quasi-judicial methods better preserves business relationships.	13	39	22	16	10
Dispute resolution avoiding judicial or quasi-judicial methods are less expensive and less time consuming for clients	17	40	29	9	5
Dispute resolution avoiding judicial or quasi-judicial methods would reduce the workload in the legal community	9	24	47	15	5
Dispute resolution avoiding judicial or quasi-judicial methods would add to the workload in the legal community	2	10	55	24	9
Compromise and settlement are the most effective means of dispute resolution	31	48	14	5	2
Legal practitioners should routinely encourage clients to choose the dispute resolution process most appropriate to their business	39	37	12	3	9
Training in the whole range of dispute resolution processes should now be a core part of a legal practitioner's university education	37	33	19	6	3
A dispute resolution approach avoiding the formal legal process should always be tried in order to avoid if possible formal proceedings	13	38	21	15	13
A structured set of legal guidelines defining these terms and their parameters would be a useful reference for application to contracts	26	49	18	6	1
The use of other means of dispute resolution as an initial approach preceding the formal legal process should be included in the Rules of Court. Time bar and prescription issues would thus have been accommodated	13	30	29	13	15
On the basis you saw it as a threat, if your views on the financial consequences were suspended, would the use of ADR be a social benefit	9	43	40	4	4

This acknowledgement however does not necessarily suggest support for consensual means of dispute disposal in itself. A number of the respondents made the point that settlement prior to formal legal proceedings was the most common outcome for litigation and their response to the question was recognition that litigation would have a detrimental effect on business relationships between parties involved in a dispute.

ADR and Clients

In terms of whether dispute resolution avoiding judicial or quasi-judicial methods are less expensive and less time consuming for clients, the majority of those who responded to the survey, 55%, supported the proposition with 17% in strong agreement (see Table 5). This finding may suggest that in some circumstances respondents would recommend mediation to clients as an alternative to more traditional methods of dispute resolution. Perhaps, where the speed and cost of settlement are important determining factors? It would be interesting to ascertain whether ADR does indeed have an overall effect by reducing the number of cases that would ultimately go through the formal tribunal process or whether by conducting a mediation or other ADR procedure during the tribunal would shorten the process; or reduce the scale of the dispute; or mitigate costs in some other way over what would have been achieved, in any event, by negotiation?

Legal practitioners and Workload

The respondents were asked whether dispute resolution avoiding judicial or quasi-judicial methods would reduce legal practitioners' workload. Around 55% of those who responded to the survey held a neutral stance of the impact of ADR on their workload, with the balance 45% strongly agreeing that their workload would be reduced (see Table 5). The informal nature of ADR procedures and the reduced barriers to entry may allow more players, outwith the legal fraternity, to participate in provision of the service, so it could be argued that there would be a reduction in workload for the legal profession. The view being expressed was perhaps an acknowledgement of the Scottish Government's objective of reducing time to settlement and process costs that may be more readily achieved by the removal or reduction of input by legal practitioners (Lynch, 2010). There is of course a counter argument that if the average cost a dispute declined access to justice would be easier thereby allowing more disputes to be processed and workload maintained at current levels. In terms of whether dispute resolution that would avoid judicial or quasi-judicial methods would add to the workload of legal practitioners, there was no clear consensus from respondents either way. It seems only small proportions of respondents held the view that it would add work, with 9% of respondents in agreement with that proposition. A significant number of respondents, 47% of respondents, took a more neutral stance when posed with question as compared to previous questions. Perhaps, this finding reflects the profile of respondents relative to their level of seniority within the profession.

Effective means of dispute disposal

The respondents were then asked whether compromise and settlement are the most effective means of dispute resolution. It would appear that 80% of practitioners in agreement with the proposition, with only 7% holding a contrary view (see Table 5). This may reflect the experience of legal practitioners in

Scotland, that most cases involving litigation settle before formal process begins. The respondents also agreed with the proposition, 51%, that practitioners should routinely encourage client to select dispute resolution process most appropriate to their business.

ADR knowledge and training

The majority of respondents considered that training in the whole range of dispute resolution processes should now be an integral part of a legal practitioner's university education. This would seem to concur with Mackie's suggestions for increased education in consensual methods of dispute disposal (Mackie (1991)). It seems that 70% of those who responded to the survey agreed with the proposition. These responses may reflect a greater interest and desire to be better acquainted with ADR procedures than previously thought. On a related issue, findings from the survey underlined the need for the Government and others involved in the promotion of ADR to better explain procedures and to a wider audience, at least within the legal fraternity: this is consistent with the recommendations of the Gill Review (Gill, 2009). Indeed, respondents agreed, 76% of respondents, that a structured set of legal guidelines incorporating terminology and parameters would be a useful reference document for the application to contracts.

Effective use of ADR

A question was posed on whether dispute resolution approach avoiding the formal legal process should always be tried in order to avoid if possible formal proceedings. The results of survey were far from conclusive with only around 50% of respondents in agreement with the proposition (see Table 5). This may reflect self-interest and to a certain extent self-preservation of those who responded to the survey. Patterson and Seabolt (2001) suggest that 'ADR adds an extra layer of doubt and intrigue to situations where there may already be considerable disagreement' (pg 391), in which case ADR may in fact exacerbate matters further worsening an already fraught state of affairs. Nevertheless, most construction industry commentators disagree with this view asserting that ADR is indeed an adjunct to other forms of dispute disposal (CIC, 2002).

ADR and the Courts

It seems that 29% of respondents to the survey strongly disagreed with the proposition that ADR should be included in the Rules of Court (see Table 5). The proposition could be read as going beyond the Woolf Reforms to the civil procedure rules in England and Wales and this may have contributed to the negative view from some of the respondents.

The opportunities and threats from ADR

In response to a question as to whether ADR constitute an opportunity or a threat to legal practitioners within Scotland, the majority of respondents, 52%, agreed that ADR was an opportunity rather than a threat; only 7% of respondents identified ADR as a threat to the legal profession (see Table 5). Interestingly when asked the question 'on the basis you saw it as a threat, if your views on the financial consequences were suspended, would the use of ADR be a social benefit?' 52% of respondents agreed with the proposition. Perhaps a more tellingly finding was that only 7% of respondents disagreed that the use of ADR

would be a social benefit (see Table 5). It could be that the perception of the legal fraternity as inherently conservative towards non-court sanctioned dispute resolution is unfounded, or that perhaps this was the most socially-acceptable response?

4 Conclusion

While a significance body of case law does exist, proceedings involving ADR are not widely disseminated seemingly amongst legal practitioners according to the survey sample. The study has also shown that Scots legal practitioners overwhelmingly agree that binding forms of dispute resolution such as adjudication and arbitration remain the most effective means of resolving construction disputes, albeit opportunities for mediation are emerging. The survey findings will hopefully provide added impetus to the debate surrounding ADR more generally, and the development of a strategy for the greater use of consensual means of dispute disposal for resolving disputes with particular reference to the construction industry in Scotland. Such a strategy will require further education & training in ADR processes among legal practitioners in addition to the wider dissemination of case law relative to the use of ADR in construction disputes.

Abstract:

The *Building and Construction Industry Security of Payment Amendment Act 2010* (NSW) ('the 2010 amending Act') was assented to on 29 November 2010. The 2010 amending Act makes changes to the operation of the *Building and Construction Industry Security of Payment Act 1999* (NSW), and is designed to enhance the ability of sub-contractors to recover payment by allowing claimants to attach moneys payable to the respondent by the respondent's principal. Currently, when, in response to a payment claim, the respondent fails to provide a payment schedule, the claimant can elect between recovering the unpaid portion of the claimed amount as a debt in any court of competent jurisdiction and making an adjudication application. If the claimant elected to recover the debt in a court, the claimant could commence proceedings in a court and apply to the court for an attachment order under s 14 of the *Contractors Debts Act 1997* (NSW). This is unchanged by the 2010 amending Act. However, if the claimant elected to go to adjudication, the claimant could not require the 'principal contractor' (i.e., the respondent's principal) to withhold payments to the respondent. The 2010 amending Act plugs this gap by establishing that a principal contractor can be required to retain sufficient money to cover the amount claimed against the respondent without requiring the claimant to go through the courts. This paper provides an analysis of the amendments introduced by 2010 amending Act and addresses the main implications of the amendments for the three parties affected, namely, the claimant, the respondent and the respondent's principal.

adjudication, amendments, New South Wales, security of payment

1 Introduction

1.1 Sub-contracting and security of payment

The Australian building and construction industry is a project-based industry and consists of a large number of small private firms (ABS, 2004). In project-based industries like the building and construction industry the delivery of projects to

clients typically requires a head-contractor to purchase 'sub-projects' and expertise from a large number of external trade suppliers. Consequently, head-contractors in the construction industry often act as 'systems integrators' and take responsibility for actively coordinating a network of sub-contractors (Martinsuo and Ahola, 2010).

According to Harris and McCaffer (2001), the practice by head-contractors of sub-contracting the works under the head-contract has been on the rise in Australia since the 1980's. However, Uher and Davenport (2009) place the shift to sub-contracting as early as the late 1960's, which was about the time when most Western economies began to experience periodic economic downturns when head-contractors' economic capacity as direct employers of tradespeople began to diminish. Harris and McCaffer (2001) and Uher and Davenport (2009) agree that sub-contracting has now become widespread in the construction industry and is an essential component of the project procurement structure and delivery process.

To appreciate how prolific sub-contracting is in the construction industry in Australian, the National Electrical and Communications Association in Australia indicates that about '95% of the labour content' on construction projects, and '75% of the total project value', is undertaken by sub-contractors (Cole, 2003). As at the end of June 2003, there were about 340,000 construction businesses operating in Australia with employment of just over 700,000 people. Trade service businesses accounted for about 270,000 (or about 80%) of all construction businesses and employed just over 500,000 people, which represents about 75% of the total construction employment. The majority of trade service businesses (about 70%) were earning an annual income of less than AU\$100,000 (ABS, 2004).

The reasons for the widespread use of sub-contracting in the construction industry are many. However, according to Goldfayl (1999), one notable advantage to head-contractors of sub-contracting relevant here is the ability of head-contractors to divest much of the financial risk of delivery of the works under the head-contract to sub-contractors – the advantage for head-contractors being improved cash flow through the effective up-front financing of the bulk of a project by sub-contractors (Maqsood *et. al.*, 2003). This reduces head-contractors' need for interim borrowings and so reduces head-contractors project costs. This, of course, makes good commercial sense for head-contractors and their clients. However, it is the systematic abuse of sub-contracting that appreciably contributes to the security of payment problem in the construction industry – the abuse being to wrongfully delay and devalue payments to sub-contractors due under the sub-contract to further enhance the financial position of the head-contractor.

Typically, construction projects are characterised by a hierarchical chain of contracts involving cascading payment obligations (Commonwealth Government, 2002). Under this hierarchical chain the Principal (sometimes called 'the Employer' or 'the Owner') pays the head-contractor, the head-contractor then pays the sub-contractor and the sub-contractor then pays sub-sub-contractors and suppliers. While money flows smoothly down the construction chain, all is well. However, all too often one party in the chain does not pay the other party for work done contrary to the contract between them. If the head-contractor wants to reduce its overdraft or is short of money, there is a temptation to delay or withhold

passing on payments down the chain. Sometimes the head-contractor will simply not want to part with money to project participants down the chain. Sometimes the head-contractor is dishonest and, in effect, takes the sub-contractor's money with no intention of ever paying the sub-contractor. Sometimes, instead of passing money down the chain, the head-contractor uses the money to pay other creditors. In any event, a delay or failure to make payments by one participant higher up in the contractual chain can create significant financial strain on many more project participants lower down in the chain. Ongoing delays or failures by a head-contractor to pass money down the chain can reduce sub-contractors' cash flow to zero. If this happens, a sub-contractor may be forced to carry bad debts, and in extreme cases, may be forced into some form of insolvency (Commonwealth Government, 2002).

The problem is not new. More than 100 years ago, the NSW Government enacted the *Contractors Debts Act 1897* as a means of providing some security of payment to workers and tradespeople during the construction of the NSW railways. The *Contractors Debts Act 1897* has since been replaced by the *Contractors Debts Act 1997* (NSW), but it has not materially altered the scheme under the *Contractors Debts Act 1897*. Section 14 of the *Contractors Debts Act 1997* (NSW) provides that if court proceedings are commenced by an unpaid sub-contractor against a head-contractor for recovery of money for work carried out or materials supplied, the court may make an 'attachment order' against the Principal. The Principal served with the attachment order has to retain from progress payments to the head-contractor sufficient money to cover the debt due to the sub-contractor. If, while the order is in effect, the Principal fails to withhold the money, the sub-contractor can sue the Principal for the amount.

If under an attachment order money is retained by the Principal, the sub-contractor upon obtaining judgment against the head-contractor asks the court for a 'debt certificate' under s 7 of the *Contractors Debts Act 1997* (NSW). If the sub-contractor serves on the Principal a copy of the debt certificate and a 'notice of claim' the effect is that the money owed by the Principal to the head-contractor is assigned to the sub-contractor. However, the *Contractors Debts Act 1997* (NSW) has been rarely used. This is because, to obtain the attachment order, the sub-contractor had to commence litigation and satisfy the court that the head-contractor owes the sub-contractor money for work carried out or materials supplied. Litigation is costly, time consuming and requires engaging a lawyer. The money is frozen in the hands of the Principal until the litigation is complete, which may be months or years. In the meantime, sub-contractors may be forced into insolvency through lack of cash flow.

1.2 Security of payment legislation in New South Wales

Following the introduction of the *Housing Grants, Construction and Regeneration Act 1996* (UK), the *Building and Construction Industry Security of Payment Act 1999* (NSW) ('the NSW Act') was introduced by the Carr Labour Government in an attempt to counter the security of payment problem in the NSW construction industry. The NSW Act was assented to on 5 October 1999 and commenced on 26 March 2000. New South Wales was the first Australian jurisdiction to introduce this type of legislation.

As a consequence of a formal review undertaken at the end of the NSW Act's first three years of operation, the NSW Act was significantly amended by the *Building and Construction Industry Security of Payment Amendment Act 2002* (NSW). The NSW Act (as amended by the *Building and Construction Industry Security of Payment Amendment Act 2002*) commenced on 3 March 2003.

The object of the NSW Act:

is to ensure that any person who undertakes to carry out construction work (or who undertakes to supply related goods and services) under a construction contract is entitled to receive, and is able to recover, progress payments in relation to the carrying out of that work and the supplying of those goods and services.¹

To achieve this objective, the NSW Act has introduced new statutory rights for claimants, such as: a right to progress payments;² a right to interest on late payments;³ a right to suspend work;⁴ and a right of lien.⁵ The NSW Act also renders void 'pay-when-paid' clauses in construction contracts.⁶ The parties cannot contract out of the NSW Act.⁷

The NSW Act also introduced a unique form of 'rapid adjudication' to deal with disputes over the amount of progress payments due, whereby an independent adjudicator makes an interim determination as to the amount of progress payment to be paid to a claimant by a respondent. Only a claimant (i.e., the person who has contracted to carry out construction work or to provide related goods and services) can initiate the adjudication process, however, both parties are entitled to make submissions to the adjudicator (subject to s. 20(2B) of the NSW Act). An adjudicator can only be appointed by an Authorised Nominating Authority (ANA) chosen by the claimant.⁸ An extended overview of the operation and performance of the NSW Act is provided by Brand and Uher (2010). A detailed review of the NSW Act, and comparable legislation operating in Australia, is provided by Davenport (2010).

Prior to the introduction of the NSW Act it was not feasible to sue for progress payments. By the time the matter was finally heard by a court, the sub-contract would be complete and any right to progress payments would be replaced by the final accounting between the parties. The sub-contractor would then want a final judgment not merely a judgment for an interim payment. The NSW Act changed that; it enables a sub-contractor to make claims for progress payments and have them adjudicated in a matter of weeks. Suddenly, it became feasible to sue for progress payments. Judgment could be obtained by simply filing an adjudication certificate. Nevertheless, whilst adjudication speeds up the passing of money down the line, it does not remove the ability of a head-contractor, in the interim, to use for the head-contractor's own purposes money which is for the sub-

⁴ *Building and Construction Industry Security of Payment Act 1999* (NSW) ss. 15(2), 16(2), 24(1).

⁵ *Building and Construction Industry Security of Payment Act 1999* (NSW) s. 11(3).

⁶ *Building and Construction Industry Security of Payment Act 1999* (NSW) s. 12(1).

⁷ *Building and Construction Industry Security of Payment Act 1999* (NSW) s. 34.

⁸ *Building and Construction Industry Security of Payment Act 1999* (NSW) s. 17(3)(b).

contractor's work. If that ability is removed, the incentive to delay and withhold the money is removed.

Subsequent to the introduction of the NSW Act, section 7(1A) of the *Contractors Debts Act 1997* (NSW) was amended by the insertion of s 7(1)(A), which provides:

If an adjudication certificate within the meaning of the *Building and Construction Industry Security of Payment Act 1999* has been filed as a judgment for a debt in accordance with section 25 of that Act, the court may, by order made on the application by the person who filed the adjudication certificate, issue a debt certificate in respect of that debt under this section.

Nevertheless, the problem still remained that to freeze moneys in the hands of the Principal until the adjudication certificate is filed, the claimant had to commence legal proceedings in parallel with adjudication proceedings. However, that would be an abuse of process; the two proceedings cannot co-exist. The consequence was that a sub-contractor was unable to freeze moneys in the hands of the Principal if the sub-contractor submitted the payment claim for adjudication. The NSW Government has now rectified the problem in the *Building and Construction Industry Security of Payment Amendment Act 2010* (NSW), which is discussed in detail below.

2 The Building and Construction Industry Security of Payment Amendment Act 2010 (NSW)

2.1 Background

In September 2010, the NSW Department of Services, Technology and Administration released a discussion paper for building and construction industry stakeholder consideration. The discussion paper identified a number of matters of concern regarding operation of the NSW Act. The discussion paper pointed to, *inter alia*, the difficulties being experienced by 'subcontractor-claimants' in securing payment after adjudication, particularly when the respondent became insolvent (DSTA, 2010).

As a consequence of the comments made by industry stakeholders in reply to the discussion paper, the *Building and Construction Industry Security of Payment Amendment Act 2010* NSW ('the 2010 amending Act') was introduced. The 2010 amending Act was assented to on 29 November 2010 and commenced on 28 February 2011. The 2010 amending Act inserts sections 26A to 26F, section 34A and Schedule 2, Part 4 into the NSW Act. The 2010 amending Act applies to existing and future construction contracts and the amendments apply to current and future adjudication applications.

The 2010 amending Act enables a sub-contractor to freeze in the hands of the Principal money that is or will become payable to the head-contractor. It enables a sub-contractor to achieve speedily, inexpensively and without a court order what an 'attachment order' under *Contractors Debts Act 1997* (NSW) previously achieved. Whereas attachment orders under the *Contractors Debts Act* (NSW)

have been uncommon, payment withholding notices under the the NSW Act are expected to be frequently used.

2.2 Payment withholding request

A sub-contractor claiming payment from a head-contractor may serve upon the head-contractor's Principal a 'payment withholding request' at any time after lodging an adjudication application. The prescribed form of payment withholding request and the standard statutory declaration that must accompany the payment withholding request are made readily available by NSW Procurement (2011). The effect of service of the payment withholding request is that while it remains effective the Principal must retain and not pass on to the head-contractor moneys owed by the Principal to the head-contractor for work carried out or materials supplied by the head-contractor. Some qualifications are discussed below.

The problem that the 2010 amending Act addresses is best explained by an example. Assume that a sub-contractor (the claimant) does \$10,000 worth of work for a head-contractor (the respondent) and at the end of the month the sub-contractor makes a progress claim. About the same time the respondent will make a progress claim against the respondent's Principal for payment for that work. If, within 10 business days after being served with the claimant's payment claim, the respondent gives the claimant a payment schedule for less than the claimed amount, the claimant can immediately apply to an authorised nominating authority to have the payment claim adjudicated. At the same time as the claimant makes the adjudication application, the amendment enables the claimant to give a payment withholding request to the Principal.

Upon receipt of the payment withholding request, the Principal must retain \$10,000 from moneys due or subsequently becoming due from the Principal to the respondent for work carried out by the claimant. If the claimant moves quickly, the claimant should be able to serve the payment withholding request before the Principal has paid the respondent. When payment cycles are monthly, this should be trouble-free. The effect is that the respondent will not be able to use the claimant's money for the respondent's own purposes.

2.3 The Principal's obligation to retain money

Under the Act the person with whom the respondent contracts to provide work or materials is called 'the Principal contractor'. That term is confusing. In this paper the term 'Principal' will be used. The Principal is the person, if any, one step up the contract chain from the respondent. If the head-contractor to the Government, an owner or developer is the respondent in an adjudication application, the Government, the owner or the developer is the Principal. If a sub-contractor to the head-contractor is a respondent in an adjudication application, the head-contractor is the Principal.

The purpose of an attachment order under s 14 of the *Contractors Debts Act 1997* (NSW) and a payment withholding request under s 26A of the NSW Act is to freeze moneys in the hands of the Principal until the claimant's entitlement to the moneys is decided by a court. To obtain payment of those moneys from the Principal the claimant must obtain a judgment and ask the court for a debt certificate under s 7 of the *Contractors Debts Act 1997* (NSW). To obtain payment from the Principal the claimant must serve on the Principal a notice of

claim in an approved form together with a copy of the debt certificate.¹ The procedure is described in detail by Davenport (2010, pp. 223-25).

If served with a payment withholding request, the Principal must act quickly to stop all payments to the respondent for work carried out or materials supplied by the respondent until the Principal can ascertain how much of those payments are for work or materials that the respondent engaged the claimant to carry out. Out of money that is or subsequently becomes payable by the Principal to the respondent, the Principal must withhold sufficient to cover the amount claimed in the payment claim. There are some qualifications. There are three ceilings on the amount to be retained. The Principal is obliged to retain the smallest of the following:

- A. the amount claimed in the payment claim the subject of the adjudication application, less any part payment made;²
- B. the amount owed, or which subsequently becomes payable, by the Principal to the respondent when or after the payment withholding request is served on the Principal;³ or
- C. the amount that is or becomes payable by the Principal to the respondent for or incidental to the work or materials that the respondent engaged the claimant to carry out or supply.⁴

A claimant may claim any amount but the amount which the Principal must retain is only the amount that is payable by the Principal to the respondent for the work or materials supplied by the claimant. For example, under the sub-contract the claimant may claim \$1m for certain piling work – this is amount ‘A’ above. Under the head contract the amount payable by the Principal to the respondent for the piling work may be only \$100,000 – this is the amount ‘C’ above. The Principal is only required to withhold payment of \$100,000 even though the Principal owes the respondent \$500,000 – this is the amount ‘B’ above. The amount by which ‘B’ exceeds ‘C’ is for work other than the work or materials carried out or supplied by the claimant. It may be for work carried out by other sub-contractors to the respondent.

The obligation to retain money does not extend to all money payable by the Principal to the respondent. It does not apply to money payable to the respondent for work carried out or materials supplied by sub-contractors other than the claimant. The obligation applies not only to payment for the work indicated in the payment claim which is the subject of the adjudication. It also applies to payment for any other work carried out or materials supplied by the claimant under the sub-contract. The application of the NSW Act to refund (by the Principal) retention moneys and security deposits may present problems.

The money which is subject to the payment withholding request is not only the amount which represents the value of that work but “money that is or becomes

¹ *Contractors Debts Act 1997* (NSW), s 6.

² *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26B(4).

³ *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26B(1).

⁴ *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26B(2).

payable...for work”.¹ That could include extra payable for delay, variations and, perhaps, damages. Section 26B(2) provides:

The amount is only required to be retained out of money that is or becomes payable by the Principal contractor to the respondent for work carried out or materials supplied by the respondent to the Principal contractor as part of or incidental to the work or materials that the respondent engaged the claimant to carry out or supply.

Note the word ‘incidental’. Assume that the claimant supplies bricks to the respondent and the payment claim is for \$1,000 for the value of the bricks. Assume that the amount payable by the Principal to the respondent for the bricks is \$1,100. The extra \$100 represents the respondent’s entitlement for profit and attendance. Assume that at the time of receipt of the payment withholding request (for \$1,000) the Principal has paid the respondent \$500 and the Principal owes the respondent \$600. It seems that the respondent must retain the \$600 even if \$100 of that could be said to be the respondent’s entitlement for profit and overheads.

Now assume that the respondent’s work involves building a house with the bricks. Assume that there are many sub-contractors and the contract price is a lump sum. Progress payments by the Principal to the respondent are payments on account of the lump sum price. It will not be possible to identify any particular amount that is payable by the Principal to the respondent for the bricks. But, ultimately, part of the contract price for the house will represent money that is payable by the Principal to the respondent for the bricks supplied by the claimant. In that situation it seems that the Principal must withhold payment to the respondent of \$1,000.

Without the consent of the respondent or a notice from the claimant attaching a debt certificate under s 7 of the *Contractor’s Debts Act 1997* (NSW) the Principal must not pay any amount to the claimant. If, prior to issue by the court of a debt certificate under s 7 of the *Contractors Debts Act 1997* (NSW), the respondent is placed in liquidation or made bankrupt, the claimant cannot obtain a debt certificate without special leave of the court. Commonwealth legislation, rather than the *Contractor’s Debts Act 1997* (NSW) and the NSW Act, then applies to moneys withheld. If, while withholding money pursuant to a payment withholding request, the Principal receives an attachment order (a garnishee order) from another creditor of the respondent, the Principal would not be able to pay the creditor out of the moneys which the Principal is required to withhold.

If after being served with a payment withholding request, the Principal is uncertain whether an amount due from the Principal to the respondent should be paid to the respondent or be withheld, the Principal should seek the opinion of the respondent and, if there is a difference of opinion, obtain legal advice. Of the two options, paying or withholding, the second involves less risk for the Principal. If the Principal wrongly withholds payment, the Principal will probably be liable to pay interest to the respondent but if the Principal pays the amount to the respondent, the Principal could be liable to the claimant for the amount and possibly interest. Section 26C of the NSW Act provides:

¹ *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26B(2).

If the Principal contractor discharges the Principal contractor's obligation to pay money owed under a contract to the respondent in contravention of a requirement under this Division to retain the money, the Principal contractor becomes jointly and severally liable with the respondent in respect of the debt owed by the respondent to the claimant (but only to the extent of the amount of money to which the contravention relates).

If an amount becomes payable by the Principal to the respondent and it must be retained pursuant to a payment withholding request, the Principal cannot discharge its obligation to the respondent by setting off an amount that subsequently becomes due from the respondent to the Principal.¹ For example, if at 30 June the respondent is entitled to a progress payment from the Principal of \$10,000 and the Principal receives a payment withholding request for an amount of \$10,000 or more, the Principal must retain the \$10,000. If subsequently, the respondent's work was found to be defective and only worth \$1,000, the Principal must still retain the \$10,000. There is no obligation on the Principal to deposit in a trust account the money withheld. However, for accounting purposes, the Principal should separately show the money withheld. Even if in the next progress valuation the work is valued at \$1,000 or, because the respondent is liable to the Principal for liquidated damages for delay, the next progress certificate shows that the respondent owes the Principal money (and the Principal does not owe the respondent any money), or the contract has been terminated by the Principal on account of the respondent's breach of contract, it seems that when the respondent receives a notice of claim and debt certificate for \$10,000 under s 6 of the *Contractor's Debts Act 1997* (NSW), the Principal must pay the \$10,000 to the claimant.

It seems that for the Principal there is one only way around the problem. That would be for the Principal to obtain a judgment against the respondent. When the Principal obtains such a judgment, it seems that the \$10,000 is no longer an amount which is owed by the Principal to the respondent. The previous debt merges in the judgment. It seems that the amount payable by the Principal pursuant to the notice of claim and debt certificate under s 6 of the *Contractor's Debts Act 1997* (NSW) could not require the Principal to pay the claimant any amount exceeding the amount owed by the Principal to the respondent under the judgment.

If a person is served with a payment withholding request and the person is not (or is no longer) a Principal contractor in relation to the payment claim, the person must give written notice to the claimant within 10 business days after receiving the payment withholding request.² A person may have once been but is no longer a Principal contractor (within the meaning of s 26A(4) of the NSW Act) because, before receiving the payment withholding request, the person has paid all moneys due from that person to the respondent and no further moneys will become due.

The Principal is not required by the payment withholding request to retain the money if 20 business days have elapsed since the Principal was served with a copy of the adjudicator's determination of the payment claim to which that

¹ *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26C(1).

² *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26A(5).

payment withholding request relates.¹ In counting the 20 business days, the date upon which a copy of the determination was served on the Principal is not counted. The Principal must allow 20 business days to pass and on the day after the 20th business day has expired, the Principal is no longer required by that payment withholding request to retain any moneys.

Section 26B(5) of the NSW Act provides that within 5 business days after the adjudicator's determination is served on the claimant (by the adjudicator) the claimant must serve a copy of the adjudicator's determination on the Principal. The Principal must not act on that. It is only for information. Even if the determination is that there is no progress payment due to the claimant, the Principal must continue to withhold payment until 20 business days have elapsed after the Principal is served with a copy of the determination.² It is always possible that within that period the claimant will commence another adjudication and serve another payment withholding request. The reason why the Principal must retain the moneys for 20 business days is to give the parties time to make applications to the appropriate court. Either party may seek orders from a court with respect to the adjudication determination. To actually have a right to recover moneys from the Principal, the claimant must obtain a debt certificate from the court.

Sometimes a respondent obtains from the NSW Supreme Court a declaration that an adjudicator's determination is void even though the adjudication application is valid. By the time that declaration is obtained, it will be too late for the claimant to withdraw the adjudication application.³ Sometimes the Court will be far sighted enough to make it a condition of the declaration that the parties agree to an extension of time for the making of an adjudication determination but often this is not the case. Then there could be a valid adjudication application but no possibility of there ever being an adjudication determination. In that event, if the respondent does not obtain an appropriate order from the Court, the Principal's obligation to retain money continues.⁴ The limitation period in s 17 of the *Contractors Debts Act 1997* (NSW) does not apply and there is no limitation under the NSW Act on how long the Principal must retain the money. This appears to be a drafting oversight. If the Principal does pay it to the respondent or uses it to discharge an obligation of the respondent to the Principal, the claimant can sue the Principal.⁵ Consequently, when a respondent seeks a decision from the NSW Supreme Court declaring an adjudication determination void the respondent should ensure that an appropriate order is made with respect to any payment withholding request that the claimant may have served or might even thereafter serve on the respondent with respect to the adjudication application.

Sometimes the claimant will not know if there is a Principal or who the Principal is. Under s 26E of the NSW Act the claimant may ask the adjudicator to request the respondent to provide information to the claimant as to the identity and contact details of the Principal. The Act does not prescribe a time for the supply by the respondent of the information. The adjudicator should state a time. If the

¹ *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26B(3)(d).

² *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26B(3)(d).

³ See: *Cardinal Project Services v Hanave* [2010] NSWSC 1367.

⁴ See: *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26B(3).

⁵ *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26C(1).

claimant thinks that there may be more than one Principal, the claimant can serve a payment withholding request on each person that the claimant believes is a Principal.

Section 7(2)(b) of the NSW Act provides that the NSW Act does not apply to a construction contract for the carrying out of residential building work (within the meaning of the *Home Building Act 1989* NSW) on such part of any premises as the party for whom the work is carried out resides in or proposes to reside in. If the contract between the Principal and the respondent is a construction contract to which the NSW Act does not apply by reason of s 7(2)(b), then the claimant cannot validly serve a payment withholding notice on the Principal; that Principal is exempt from the NSW Act.¹

If the claimant withdraws an adjudication application under s 26(2)(a) of the NSW Act, and makes a new adjudication application under s 26(2)(b), the claimant must give any Principal who has been served with a payment withholding request notice of the withdrawal.² A payment withholding request based upon the original adjudication application (now withdrawn) would not apply to the new adjudication application. The claimant would have to serve a new payment withholding request.

Section 26D of the NSW Act provides some protection for the Principal against claims by the respondent. While the statutory obligation to retain money continues, it acts as a defence to a claim by the respondent against the Principal for the money.³ Any period during which the Principal retains money pursuant to the obligation is not to be taken into account for the purposes of reckoning the period for payment by the Principal of the respondent.

The respondent could not claim interest from the Principal for the period during which the Principal lawfully withheld payment. If the respondent made a claim under the NSW Act against the Principal, in calculating the due date for payment of the amount withheld, time for payment would not run during the period that the Principal withheld payment in compliance with a valid payment withholding request.

The Principal should only make a payment to the claimant with the consent of the respondent or pursuant to a notice under s 6 of the *Contractors Debts Act 1997* (NSW) attaching a copy of debt certificate from a court. If a payment is made pursuant to the court's debt certificate, the *Contractors Debts Act 1997* (NSW) provides protection for the Principal.

When a contract between the Principal and the respondent provides that the Principal can retain moneys (retention moneys) from payments to the respondent, it may be prudent to have an express provision that moneys retained in accordance with a statutory requirement are not to be considered to be part of the retention moneys which the Principal is entitled to retain.

¹ *Building and Construction Industry Security of Payment Amendment Regulation 2011* (NSW).

² *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26D(3).

³ See: *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26D(1).

The Principal's obligation to withhold money can be discharged, in whole or in part, if the respondent pays an amount to the claimant or, with the authority of the respondent, the Principal pays an amount to the claimant.¹ In addition, the Principal is entitled to rely in good faith on a statement in a statutory declaration by the respondent that a specified amount claimed has been paid to the claimant.² A prudent Principal would check with the claimant before releasing any amount to the respondent.

Finally, the Principal's obligation to withhold money is discharged if the adjudication application is withdrawn.³ The term 'withdrawn' is not defined. Withdrawal of a payment claim or the payment withholding request is not the same as withdrawal of an adjudication application. Section 26D(4) provides that the Principal is entitled to rely in good faith on a statement in a statutory declaration by the respondent that an adjudication application has been withdrawn. The claimant can at any time notify the Principal that the claimant withdraws the payment withholding request. A statement by the claimant to the Principal that the claimant withdraws the payment claim would effectively be notice that the claimant withdraws the payment withholding request.

3 Concluding remarks

The 2010 amending Act follows the release of a discussion paper by the NSW Department of Services, Technology and Administration in September 2010 as part of a formal review of the NSW Act. The amendments aim to improve security of payment by addressing difficulties experienced by 'subcontractor-claimants' in securing payment after adjudication and accessing the benefits of the *Contractors Debts Act 1997* (NSW).

The 2010 amending Act enables a claimant to 'freeze' money in the hands of the Principal that is owed to the head-contractor under the head-contract. The effect of the procedure under the 2010 amending Act is similar to that under the *Contractors Debts Act 1997* (NSW), but has been made more accessible to sub-contractors electing to go to adjudication under the NSW Act. Whereas a claimant could not previously compel a Principal to withhold payments to the respondent if the claimant elected to go to adjudication, the 2010 amending Act establishes that a Principal can be required to retain sufficient money to cover the amount claimed against the defaulting respondent without requiring the claimant to go through the courts. This means that claimants now have the ability to secure the claimed amount from the Principal immediately after an adjudication application has been made and ahead of any determination made by the adjudicator of that application. The 2010 amending Act, thus, adds appreciably to the scope of the NSW Act.

For head-contractors, the 2010 amending Act gives sub-contractors direct influence over the cash flow of head-contractors albeit within the relatively short time frame prescribed by the 2010 amending Act. Thus, the NSW Act is likely to further encourage timely negotiation between the parties over payments and early settlement of payment disputes.

¹ See: *Building and Construction Industry Security of Payment Act 1999* (NSW), ss 26B(4) and 26B(3)(a).

² *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26D(4).

³ *Building and Construction Industry Security of Payment Act 1999* (NSW), s 26B(3).

The 2010 amending Act has, for the first time, brought Principals squarely into play when it comes to payment disputes between the parties one step down in the contractual chain. A failure by the Principal to comply with the obligation to withhold money pursuant to a payment withholding request renders the Principal jointly and severally liability (with the Respondent) to pay the adjudicated amount to the extent of any failure by the Principal to withhold the money. For that reason, Principals should have adequate internal mechanisms in place to ensure that any payment withholding request promptly comes to the Principal's notice.

Case Study: Developing Admission Criteria for SAICE Adjudicators

Ntsoli Maiketso¹

¹Trans-Caledon Tunnel Authority (TCTA), Centurion,
South Africa

Email: nmaiketso@tcta.co.za

Abstract:

Adjudication is a relatively new method of alternative dispute resolution in the South African construction industry. There are low levels of knowledge and use of adjudication. There are not enough Adjudicators in the industry, and there is no established framework for skills and training. It is generally considered that the introduction of Payment and Adjudication legislation can improve the situation.

The author and others have endeavoured to improve the practice and study of adjudication in the construction industry, and have continued to publish and engage in other ways with industry bodies in this pursuit. In order to develop Adjudicator Admission Criteria for the South African Institution of Civil Engineering (SAICE), the author undertook limited research, drafted the admission criteria and sourced comment on this from key industry role players.

Criteria which were supported the most included experience, construction law and formal assessment. Objectivity of criteria was the most recurring theme, which led to the conclusion that the criteria as they are can only be regarded as interim, whilst a longer-term solution is being developed based on formal assessment.

Keywords:

adjudication, admission criteria, alternative dispute resolution, skills

1 Introduction

This paper outlines an investigation into adjudicator skills and training, presents how each admission criteria considered was identified, reviewed and subsequently modified where necessary to finalize the SAICE adjudicator admission criteria. Comments received are analysed to identify trends and themes, and conclusions are drawn where appropriate.

2 Literature Review

2.1 Fundamentals of admission criteria

The Oxford Dictionary (2000) defines admission as entering or being allowed into a building, society or school. Requirements for admission can vary from one extreme to the other, from one's origins, appearance, place in society, educational background, to professional achievements and national honours. For example, whilst admission to a primary school may only require that the place of residence be within a certain radius from the school, admission to a post-graduate programme at a university may require a completely different set of attributes like experience, leadership and intellectual capability.

Admission into professional societies is also varied, depending on whether these are statutory bodies or voluntary associations. Statutory bodies are normally regulated from the minimum educational qualification required, the type and length of experience, and any examination or peer review mechanism employed. An examples is the Engineering Council of South Africa, which is regulated by the Engineering Profession Act No. 46 of 2000. Voluntary associations such as SAICE on the other hand have admission criteria defined by the society itself, with the only proviso typically being that such criteria should not be in conflict with its founding constitution. The subject of the paper relates to the latter.

2.2 SAICE in the South African Construction Industry

The South African construction industry is generally broken up into the building and engineering construction sectors. There are other related sectors and disciplines (quantity surveyors, architects, engineers, project managers, etc.) which together comprise what has come to be known as the Built Environment, including various bodies operating at different levels, from statutory bodies to voluntary associations, of which SAICE is one. Amongst the aims and objectives of SAICE, the following is relevant for this paper:

...to promote the science and practice of civil engineering.

In keeping with this noble aspiration, SAICE recently introduced a new version of its 'General Conditions of Contract for Construction' (GCC 2010), and this introduces dispute resolution by adjudicators and/or dispute boards, whose nomination can be referred to the SAICE President by the contracting parties.

SAICE enjoys wide recognition from other industry bodies, such as the Construction Industry Development Board (CIDB) and the Engineering Council of South Africa (ECSA), and it plays a critical role in the development of industry norms, guidelines and regulations. This is part of the reason why the idea of an industry-wide centre for dispute resolution has been mooted in many of its proceedings under the dispute resolution portfolio. The paper will however, only consider dispute resolution within the ambit of SAICE, in particular with regard to adjudicators and how these are admitted onto the SAICE President's List. (Discussions regarding the centre are being pursued separately).

Whilst general membership of SAICE has quite straightforward admission criteria, to serve on the SAICE President's List of Adjudicators has its own different admission criteria due to the specialised nature of the skill required.

2.3 Knowledge, skills and training on adjudication

Adjudication is a relatively new method of alternative dispute resolution in the South African construction industry. Maritz (RICS, 2007) concluded that there were low levels of knowledge and use of adjudication. Maiketso and Maritz (RICS, 2009) concluded that there were not enough Adjudicators in the industry, and that there was no established framework for skills and training.

Some research undertaken into skills and training on adjudication in South Africa showed that:

Adjudicators need an “adjudication qualification”, in addition to their professional qualification (Maritz, 2007).

In trying to unpack the finding above, further research (Maiketso, 2008) showed that the following amongst other findings:

- There was a need to establish a framework for skills and training, including provision for accreditation;
- There was general agreement on relevant skills, useful techniques and desirable personal attributes of adjudicators;
- There was broad agreement on the possible content of an “adjudication qualification” if it were to be implemented, from the acquisition of knowledge and experience, to the assessment and accreditation of competence.

The foregoing references amongst others supported the introduction of Payment and Adjudication legislation to improve the situation. Efforts are starting to be put into the conception of this mammoth task, but until such legislation is introduced together with guidelines or regulations on all of the above aspects, each sector of the industry has to address its needs as it best sees fit. The CIDB provides guidance on this matter and therefore was relied upon in developing the SAICE admission criteria, together with the Institute of Civil Engineers (ICE, UK) admission criteria.

A comparison was also made between *skills and training* information sourced from selected institutions associated with adjudication, i.e. CIDB, ICE (UK), Chartered Institute of Arbitrators (CI Arb, UK), Dispute Resolution Board Foundation (DRBF, USA), Queensland subordinate legislation for adjudication qualification (Australia), Construction Industry Council (CIC, UK), American Association of Arbitrators (AAA, USA), Federation Internationale des Ingenieurs-Conseils (FIDIC) and others. This is presented in Table 1 below (after Maiketso, 2008). General findings from these showed that experience and professional registration appear to be widely accepted or assumed where not specified, and knowledge of the relevant conditions of contract is also taken for granted. Whilst attendance of a relevant course was considered to be adequate by a few institutions, the general trend appeared to be moving towards formal tuition and peer review to facilitate accreditation.

It is with these considerations in mind that the SAICE adjudicator admission criteria were developed.

Table 1: Information from selected institutions on skills framework and accreditation for adjudicators (after Maiketso, 2008)

Institution	Experience	Registration	CoC	Course	Assignment	Examination	Interview
CIDB	PM past 5 yrs 45 yrs age	10 yrs standing	Recom	written appl			x 1
ICE	10 yrs PM In past 15 yrs	10 yrs standing	required	x 1		x 1	x 1
CIArb			required	x 3 modules	x 2	x 2 modules	x 3 days
Queensland			required	x 18	x 1	x 1	
CIC		RICS, RIBA, ICE, CIArb, CIOB					
DRBF		Attributes only					
AAA	10 yrs snr	As appropriate	Recom	Recom			
FIDIC			required	written appl	x 2	x 2	x 2 days

Abbreviations used in table:

PM – Project Manager; yrs – years; CoC – Conditions of Contract; Recom – Recommended; appl – application; snr – senior

3 Research Methodology

Purposeful sampling was adopted due to the specialised nature of the research subject. Initially theoretical sampling was used to obtain all relevant views, and subsequently discriminant sampling was used to obtain closure. Having drafted the criteria, a selected sample of industry role-players was used to source comment, and the outcome was then subjected to further internal review from within the Project Management and Construction Division (PMCD) of SAICE.

The criteria were first drafted based on two key reference documents:

- CIDB *Best Practice Guideline #C3 Adjudication, 2005; and*
- ICE *Requirements for entry onto ICE's List of Adjudicators, 2006.*

Key considerations were that these should define minimum requirements in the following aspects:

- Experience;
- Professional registration; and
- Forms of contract, construction law and adjudication.

Work in developing the first draft commenced in 2008. PMCD was afforded an opportunity to provide initial comment on this and suggest direction in terms of sourcing further comment. As background, PMCD was also provided with the full version of Table 1 to provide context.

The following institutions were then approached for comment, and feedback was received at the times shown:

- SAICE PMCD (internal), Jan-Feb2009, Sep-Oct 2009;
- Association of Arbitrators (Southern Africa) (AASA), Oct-2009;
- Dispute Review Board Foundation (DRBF) local chapter, Nov-2009;
- South African Federation of Civil Engineering Contractors (SAFCEC), Feb-2010;
- Consulting Engineers South Africa (CESA), April 2010; and
- Construction Industry Development Board of South Africa (CIDB), June 2010.

The final draft is included in the Appendix, following the incorporation of comments, as reflected under the next section (Results). In keeping with standard research ethics, confidentiality was maintained and privacy of the respondents was respected in the presentation of results.

Data handling was mostly based on content analysis. Data was organized and classified into common themes; an attempt was then made to synthesise the emerging trends into a whole, so that conclusions and/or generalisations could be drawn where possible.

To provide safeguards to the case study, as recommended by Leedy and Ormrod (2005), the following disclosures would be in order:

- Attention was paid to any contradictory comment and/or conclusion, in order to validate the overall results and not simply dismiss it as insignificant; and
- Bias, beliefs or values may have played a role, as the author is responsible for the dispute resolution portfolio within SAICE PMCD, and as such had a direct interest in the positive outcome of the exercise, to enable the criteria to be implemented.

It is trusted that these will not have unduly compromised the results and/or conclusions, and that the outcome can still lead to meaningful debate, even if the research itself may be lacking in academic rigour and impartiality.

4 Results

The results presented below are in the form of comments made, compared against corresponding changes in the original criteria circulated for comment. Where a change was not considered necessary, a reason is provided. The last column headed “type” relates to the content analysis that follows in Figure 1, which is based on the concept(s) found in the comment and to some extent in the change made / reason given.

Table 2: Comments and changes/reasons

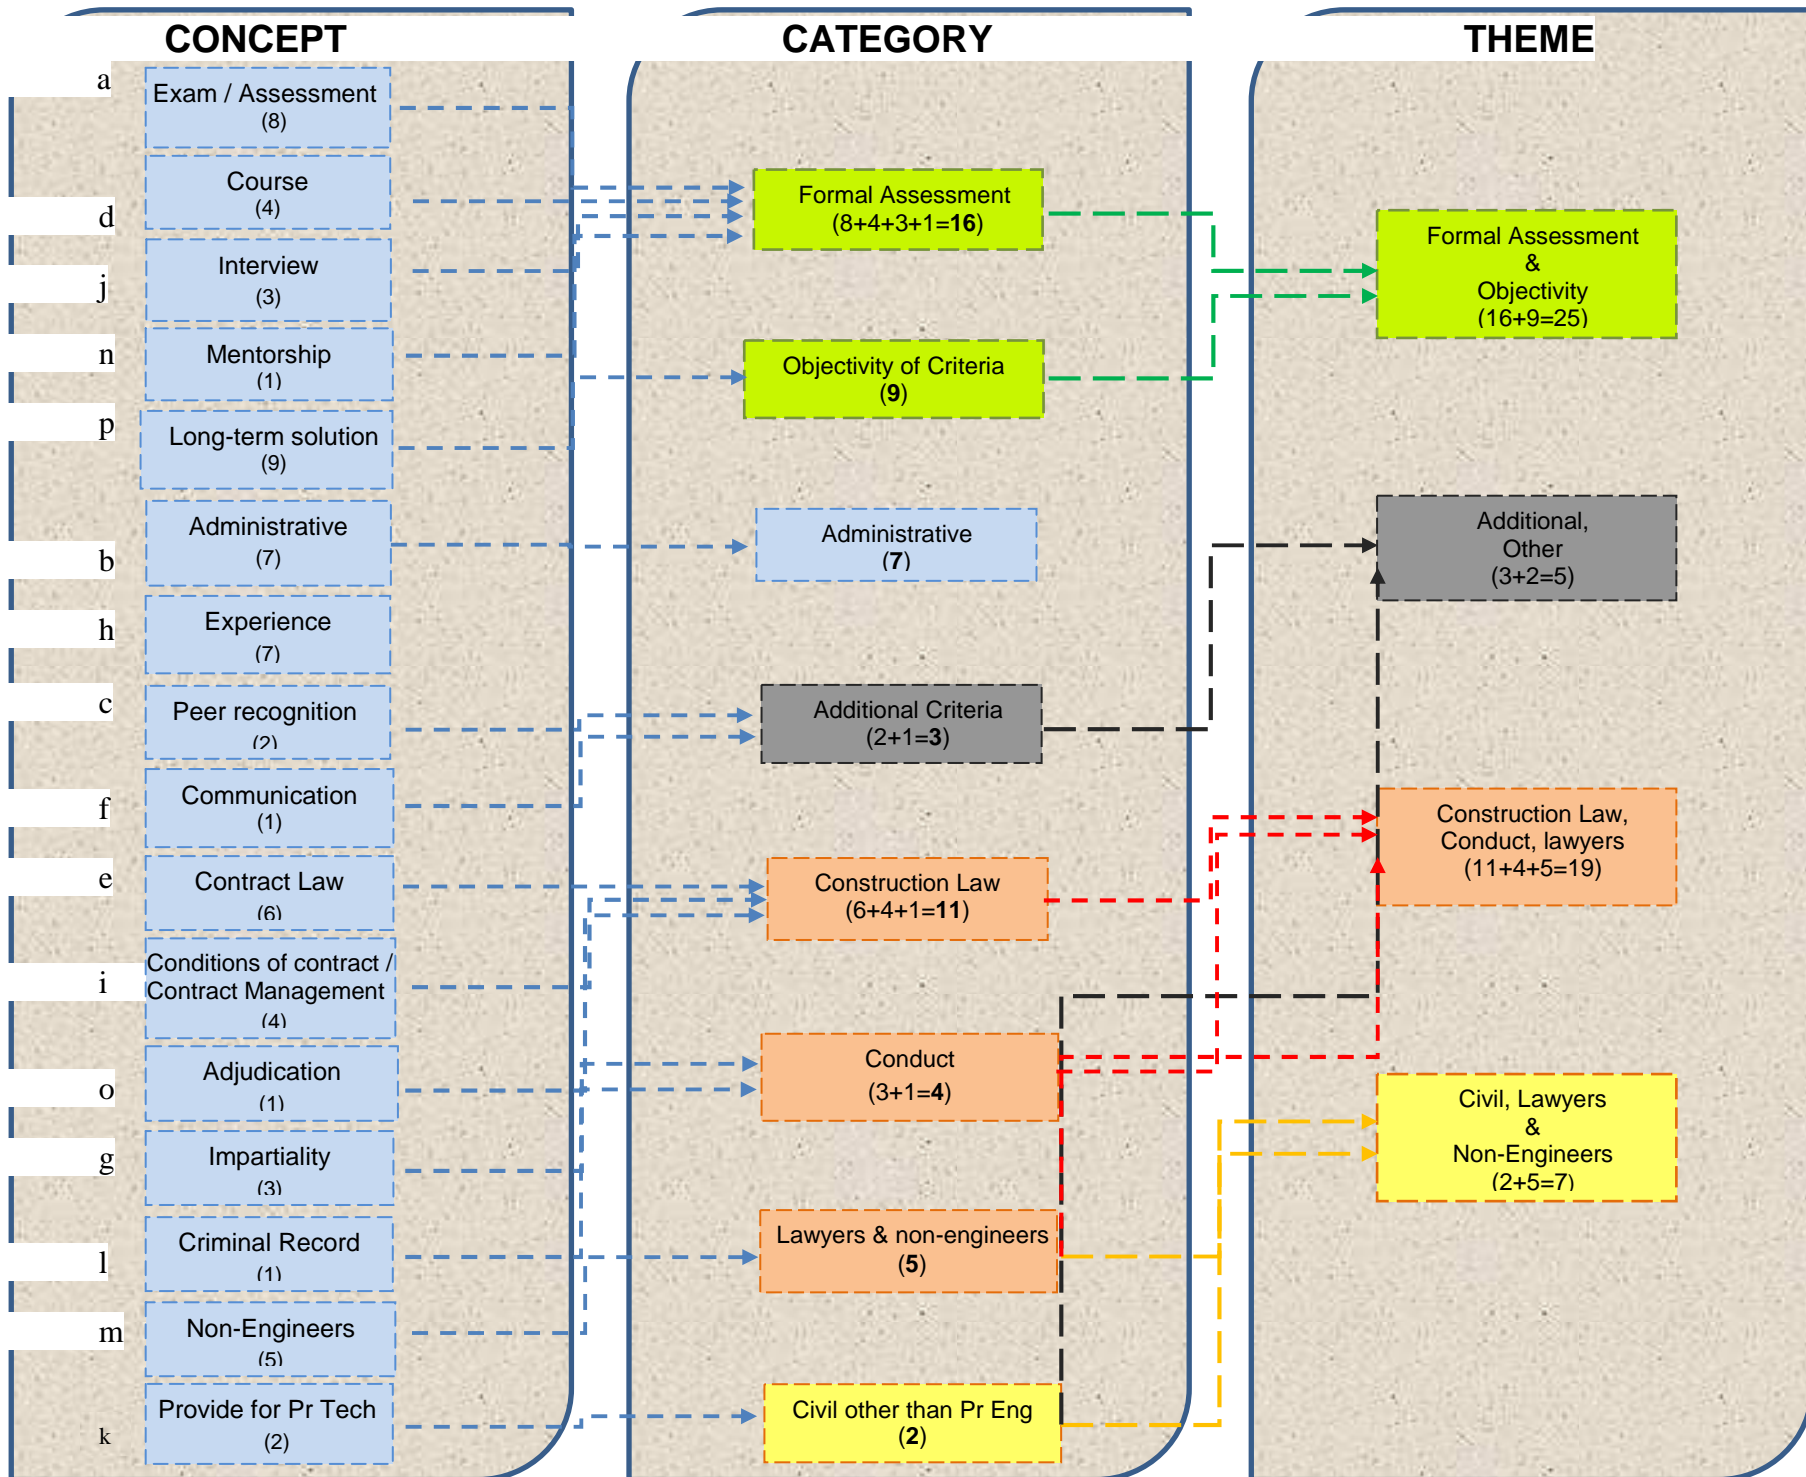

Comments raised	Corresponding changes made / reasons if not changed	Type
1. Exam not supported: could discourage senior applicants and needs much work in developing it, interim solution required	1. Exam initially removed, subsequently reinstated in the long-term, interim solution provided via sunset/transitional clause	a, p
2. CPD requirements needed for those on list	2. No change: administrative aspects of running the President’s list	b
3. Qualifications need to be defined for Panel members	3. No change: administrative aspects of running the President’s list	b
4. Include “Fellow of SAICE” or similar, to emphasize peer recognition and respect within the industry	4. No change: SAICE resolved not to use professional honours/peer recognition as an exclusionary criterion	c
5. Are there suitable courses?	5. No change: several courses available, suitability unconfirmed	d
6. Include knowledge of contract law and procedure	6. Adopted knowledge of contract law, but not of procedure (rules of natural justice applicable instead)	e
7. Include knowledge of the English language	7. No change: communication skills considered to be covered by Pr Eng and experience requirements	f
8. Include impartiality	8. Impartiality added to fairness and independence	g
9. Formal qualification via course and exam supported only if courses available in RSA	9. Initially watered down, then removed, but subsequently reinstated as part of long-term solution	a, d, p
10. Include holding of senior position for approx. 10 yrs	10. No change: post Pr Eng experience requirement considered to be adequate	h
11. Include knowledge of conditions of contract, which must be examined	11. Adopted, and referred to SAICE GCC in particular, exam retained for the longer term	i, a, p
12. Make exam/interview discretionary if application/CV does not provide evidence of competence	12. No change: requirements and application of exam / interview to be defined in the longer term, but would be made standard not discretionary	a, j, p
13. Make exam/presentation mandatory, as adjudication itself requires studying a case, interviewing the disputing parties and presenting a ruling	13. Exam/interview reinstated in the longer term, current arrangement transitional whilst exam/interview requirements are being developed	a, j, p
14. Reduce experience requirement from 10 to 5 years	14. No change: 10 years post Pr Eng experience considered necessary	h

Comments raised	Corresponding changes made / reasons if not changed	Type
15. Remove professional registration or include other professional categories besides Pr Eng, e.g. Pr Tech	15. No change: retained <i>Pr Eng or equivalent</i> to provide for Pr Tech <i>et al</i>	k
16. Must not have criminal record	16. No change: “must not have” criteria not included	l
17. Must have legal qualification, with experience in construction	17. No change: knowledge of construction contract law and conditions of contract considered adequate	e, h, i, m
18. Knowledge of contract law essential	18. Adopted	e
19. Be capable of fair, impartial and sound judgment	19. Impartiality added to fairness and independence, adjudication requires reasoned decision (in response to sound judgment)	g
20. Knowledge of construction regulations, procurement processes, and Constitution of country	20. No change: knowledge of construction contract law, conditions of contract and adjudication considered adequate, supporting laws and regulations to be more fully defined in the longer term	e, h, i, m
21. Include lawyers, do not limit to Pr Eng	21. No change: SAICE resolved to remain within its jurisdiction of civil engineering (industry-wide centre for dispute resolution being pursued separately)	m
22. Include knowledge of construction contract law and rules of natural justice	22. Adopted	e
23. Fairness and independence can be claimed by any applicant, not easy to assess	23. Impartiality introduced, key consideration being to avoid conflict of interest/bias	g
24. Assessment must allow demonstration of potential for those who haven’t done adjudications, and example adjudications for those who have	24. No change: to incorporate assessment in formal process to be adopted in the longer term	a, o, p
25. Applicants to show appreciation of tight time constraints of adjudication	25. No change: familiarity with adjudication considered sufficient	o
26. Include lawyers and claims consultants, do not limit to civil engineers	26. No change: SAICE resolved to remain within its jurisdiction of civil engineering (industry-wide centre for dispute resolution being pursued separately)	m
27. Increase experience from 10 to 15 years	27. No change: 10 years post Pr Eng experience considered sufficient	h
28. Fellow of SAICE not pre-requisite, experience and contract management enough	28. No change: SAICE resolved not to use professional honours/peer recognition as an exclusionary criterion	c, e, i
29. Course/exam not supported, will put potential applicants off	29. Exam/course removed for now, to be adopted in the longer term	a, d
30. Most appointments are done by personal reference not via these lists	30. No change: Emphasises need to regularise, status quo not optimal	b
31. Course needs careful consideration, many available, but none sufficient	31. Course removed for now, to be adopted in the longer term	d
32. Review panel to consist of experienced adjudicators	32. No change: administrative aspects of running the President’s list	b

Comments raised	Corresponding changes made / reasons if not changed	Type
33. Accept or interview applicant depending on strength of CV	33. No change: acceptance criteria defined for now, interview to be adopted in the longer term as part of the formal process	j, p
34. Pay annual fees to stay on the list	34. No change: administrative aspects of running the President's list (currently not applied for mediators and arbitrators, but may consider in future)	b
35. Provide for mentorship to facilitate training and experience	35. No change: further unpacking of skills and training to be addressed in the longer term	n, p
36. Include other built environment professionals, not limited to Pr Eng	36. No change: SAICE resolved to remain within its jurisdiction of civil engineering (industry-wide centre for dispute resolution being pursued separately)	k, m
37. Remove length of professional membership, as experience is addressed elsewhere	37. No change: post Pr Eng experience requirement considered to be necessary to ensure adequate seniority, and the two length requirements (i & ii) are not mutually exclusive	h
38. Provide for specialisation	38. No change: administrative aspects of running the President's list – on application form, as done for mediators and arbitrators	b
39. Consider geographic location	39. No change: administrative aspects of running the President's list – when selecting, proximity to disputing parties considered	b
40. Minimum requirements must be objective, assessment criteria must be in keeping with CIDB guideline, avoid vague and subjective criteria which could be open to abuse	40. Criteria qualified as a transitional arrangement whilst a formal accreditation / admission process (course/exam/interview) is being developed	p

The results above were then grouped according to key concepts identified to enable a content analysis below in Figure 1 (the numbers in brackets are the frequencies).

Figure 1: content analysis

5 Discussion

From the results above, the following observations can be made at the Concept level:

- The most numerous comments were made in connection with the long term solution, followed by exam, experience and administrative aspects.
- The least number of comments were made in connection with additional criteria of communication, criminal record and mentoring.

The following patterns emerged from a categorisation of the concepts:

- The most conceived Category was formal assessment, followed by construction law and objectivity of admission criteria.
- The least conceived Category of criteria was other professional designations besides Pr Eng, followed by conduct and other additional criteria.

Further synthesis revealed the following Themes out of the broad categories formulated above:

- The most common Theme was objectivity of admission criteria, as supported by formal assessment and the need for a long term solution.
- The second most common Theme relates to law, as supported by construction law, conduct and reference to lawyers (reference to lawyers given dual treatment, both in the positive and in the negative: for confirming additional qualifications and as a basis for exclusion).

Although it is recognised that the sourcing of comments was not on a ‘clean slate’ basis as standard research would require, as the draft criteria on which the respondents had to comment already influenced them to think in a certain way; their responses are nonetheless useful in terms of whether they support or do not support the fundamental requirements. This recognition therefore necessitated the following further analysis of the data, which was undertaken to ascertain which fundamental requirements had been most supported, and which had been the least supported, in the original draft of the admission criteria as circulated for comment:

- The most commented-upon criterion was formal assessment, as shown by reference to exam, course and interview: only four out of twenty-five comments did not support this criterion, and the rest either supported, conditionally supported, or provided suggestions/advice on how it could be implemented.
- The least questioned criterion was experience, as shown by almost no dispute being raised for the requirement for familiarity with the construction process. Although the length of experience was questioned in two instances (one to increase it, the other to decrease it), the content of the necessary experience

was not disputed. This however, cannot be considered to be a positive confirmation of whether the criterion is supported or not supported, but can be viewed more as a silent affirmation.

- The least supported criterion appears to have been to widen the net to include lawyers and others: there was strong support and motivation for SAICE to remain within its jurisdiction of civil engineering (whilst not abandoning the pursuit of an industry-wide dispute resolution centre as a separate exercise).

It is further instructive to note the high level of interest in how the panel is constituted and operates (administrative aspects), as this would be responsible for putting these criteria into effect. Perhaps because of the long-decried fragmentation of the construction industry on dispute resolution and other contractual matters, the industry needs assurance that SAICE knows what it is doing, and that such fragmentation must not simply be replaced by half-baked solutions or over-regulation without properly thinking through the full process requirements.

6 Conclusion

The results therefore appear to lead to the conclusion that the admission criteria in their current form cannot be considered as final, and that more objectivity needs to be introduced to achieve this. It is considered that such objectivity will be achieved through a formal assessment process involving a course, exam and/or interview process.

This conclusion led to the introduction of a “sunset clause”, and an interim application period during which a longer-term solution must be developed.

7 Recommendation

The following recommendations are therefore made:

- That SAICE adopts the proposed current adjudicator admission criteria as an interim measure to introduce a measure of organisation into the process of adjudication and adjudicator selection in civil engineering construction contracts.
- That SAICE develops robust formal assessment criteria involving a course, a qualifying exam and/or an interview to be implemented in the long term.
- That SAICE publicises these measures and invites interested parties to participate in charting the way forward.

INTERIM ADMISSION CRITERIA FOR SAICE ADJUDICATORS

(2011 – 2014)

9 Requirements for persons wishing to be considered for inclusion in the SAICE President's List of Adjudicators, to be applied in the period 2011 to 2014 until final criteria are developed

9.1 Introduction

This document is based on the following documents, for which the relevant institutions have granted their kind permission:

CIDB Best Practice Guideline #C3 Adjudication, 2005

ICE Requirements for entry onto ICE's List of Adjudicators, 2006.

SAICE can nominate adjudicators in terms of the SAICE General Conditions of Contract and maintains a President's List of adjudicators for this purpose (the List), as well as to facilitate adjudicator selection by Employers and/or Contractors. Admission to the List does not guarantee that any nomination will be made or that appointments will follow.

SAICE sets requirements for admission to the List and for maintenance of a name on the List.

Candidates wishing to be selected for the List must complete the standard SAICE application form for Mediators, Arbitrators and Adjudicators, and satisfy the SAICE's Dispute Resolution Panel that they meet minimum requirements stipulated below. Failure to demonstrate the necessary competence may result in one of two options:

Where clarification is required, the applicant may be invited for an interview

Where certain requirements have not been met, a response will be issued specifying this.

The SAICE Dispute Resolution Panel's (the Panel's) decisions on all such matters are final.

9.2 Minimum Qualification Requirements for Entry onto the SAICE President's List of Adjudicators

Applicants should:

have worked as Project Manager, Contract Manager, Engineer, Principal Agent or equivalent on engineering construction projects for a period of at least 10 years, preferably within the past 5 years, with appropriate disputes experience;

- (i) be registered as a Professional Engineer or equivalent of at least 10 years standing.

have detailed working knowledge of at least one, and preferably more, of the standard forms of contract recommended by the CIDB, in particular the General Conditions of Contract published by SAICE (including the adjudication provisions);

have working knowledge of international and local practice, legislation and institutional guidelines on adjudication, including CIDB guidelines;

have working knowledge of construction contract law and rules of natural justice

have appreciation of:

the factors that affect construction costs

investigations, design, construction and fabrication methods

programming and delay assessment

resource and risk assessment;

be impartial and capable of fair and independent judgment;

if invited for an interview, be able to satisfy the panel that they are a suitable person who has achieved the necessary level of knowledge of construction and dispute resolution and possesses the necessary personal management and communication skills to conduct an adjudication.

9.3 Sunset clause / interim application period

This document shall apply for a maximum period of three (3) years beginning from 2011, in which time SAICE shall develop more objective assessment criteria to be applied for all new applicants. These shall include but not be limited to the establishment of requirements for:

Written application

Passing Adjudication course(s) and / or Qualifying Examination

Panel interview

Statutory Adjudication in New South Wales: Operational Problems and Potential Improvements

Abstract:

The Australian state of New South Wales (NSW) was the second jurisdiction in the common law world and the first in Australia to introduce statutory adjudication. Although being modelled after the UK statutory adjudication regime, there are significant differences in the NSW regime that make it distinctive. The NSW regime is essentially a neutral certification process conducted by an adjudicator whose role is that of a certifier. However, due to its rapid nature and judicial interventions, there have been some serious problems with regard to the operation of the regime. This paper attempts to identify the operational problems of the NSW regime from neutral (adjudicator) and user (legal representatives in adjudication) viewpoints, allowing for the establishment of potential improvements to the current regime. The first stage involved a review of the relevant literature, parliamentary speeches and consultation documents, cases on statutory adjudication, and expert commentaries. It was followed by qualitative interviews with 11 leading adjudicators and construction lawyers who represent parties in adjudication proceedings. The main problems identified are court involvement, invariability in the quality of adjudicators, rubber stamp approach and the accessibility of the NSW Act. It is established that the introduction of a dual system of adjudication and an adjudication registry could solve most of the problems identified above.

Keywords:

adjudication, cash-flow, construction contracts, disputes, payment.

1 Introduction

New South Wales was the first jurisdiction in Australia to introduce statutory adjudication when the Building and Construction Industry Security of Payment Act¹ (the NSW Act) was on the statute books in 1999. Historically, statutory adjudication in the common-law world was first introduced three years earlier in the United Kingdom, when the Housing Grants Construction and Regeneration Act (the UK Act) was passed. Despite following the UK government's footsteps in introducing statutory adjudication,

¹ The NSW Act has been amended twice since its inception. The first once was in 2002 and the second was once in 2010.

the NSW State Government established a completely different scheme of adjudication in terms of procedure and application in its construction industry. The stark difference between the UK and the NSW adjudication schemes is that the latter imposes a reference to 'rapid mandatory adjudication' contingent on the crystallisation of progress payment disputes as prescribed by the NSW Act, whilst the former was designed for adjudication to be independent of payment. In other words, the UK adjudication model caters to all types of disputes as long as they arise under the contract, whereas the NSW model confines its application exclusively to progress payment disputes as established by the NSW Act. The UK adjudication model has been adopted (with modifications) in New Zealand,¹ a few Australian states (Western Australia² and the Northern Territory³), and the Isle of Man,⁴ whereas the NSW adjudication model appears, to varying degrees, has been emulated by a number of Australian states (Victoria,⁵ Queensland,⁶ Tasmania,⁷ the Australian Capital Territory,⁸ and South Australia⁹) and Singapore.¹⁰ The adjudication regimes in Western Australian and Northern Territory which are closely modelled after the UK regime are collectively referred to in industry parlance as *the west coast model* whereas those states and territories in Australian whose their adjudication regimes are largely based on the NSW regime are together known as *the east coast model*.

The difference in terms of adjudication operations in New South Wales and the UK is understandable, since the objectives of both Acts that underpin adjudication in these jurisdictions are fundamentally different. As stated by the then Construction Minister Nick Raynsford the objectives of the UK Act were:

First of all, it is necessary to address serious payment problems affecting many in the industry - particularly smaller firms. I receive a steady stream of mail from firms facing unnecessary hardship and even insolvency because they have not been paid for work carried out in good faith. This legislation will help to protect such firms from this sort of bad practice. Second, the legislation will address the problem of the costs and delays currently involved in settling even the most straightforward construction disputes. The legislation offers a quick means of resolving disputes so work can continue on site without delay and disruption.¹¹

² Construction Contracts Act 2004, Western Australia, Australia.

³ Construction Contracts (Security of Payments Act) 2004, Northern Territory, Australia.

⁴ Construction Contracts Act 2004, the Isle of Man.

⁵ Building and Construction Industry Security of Payment Act 2002 amended in 2006, Victoria, Australia.

⁶ Building and Construction Industry Payments Act 2004, Queensland, Australia.

⁷ Building and Construction Industry Security of Payment Act 2009, Tasmania, Australia.

⁸ Building and Construction Industry (Security of Payment) Act 2009, Australian Capital Territory.

⁹ Building and Construction Industry Security of Payment Act 2009, South Australia.

¹⁰ Building and Construction Industry Security of Payment Act 2004, Singapore.

¹¹ 'Laying Down the Law'; Building; 17 April 1998.

Conversely, Morris Iemma the Minister for Public Works and Services of New South Wales had this to say:

The main thrust of this bill is to reform payment behaviour in the construction industry. The bill creates fair and balanced payment standards for construction contracts. The standards include use of progress payments, quick adjudication of disputes over progress payment amounts and provision of security for disputed payments while a dispute is being resolved. The bill will speed up payments by removing incentives to delay.¹

The objective of the NSW Act is thus clear, i.e., to improve payment practices in the construction industry. Adjudication under the NSW Act is merely a tool to achieve its policy objective. Conversely, the objective of the UK Act is two-fold. It first attempts to improve cash flow in the construction industry. Its other objective is to improve the efficiency of dispute resolution in the construction industry.

Since the objective of the NSW Act is different from its UK counterpart, its adjudication regime has been designed to be prescriptive, with strict and tight time frames for each step in the adjudication process, from the nomination of the adjudicator until the delivery of the decision. The scope of this regime's application is also considerably narrower than that of the UK regime. Only disputes on progress payments as crystallised under the NSW Act can be referred to adjudication. The definition of progress payments as prescribed by the NSW Act is, however, wide enough to include final payments.² Based on the take-up rates published by the NSW Department of Commerce, it may be inferred that statutory adjudication has been effective in New South Wales (Coggins et al, 2010). This supports the notion that, if adjudication is not effective, industry participants will simply not use it.

The success of statutory adjudication in New South Wales, however, is not without its challenges. The adjudication system underpinned by the amended NSW Act seems to have drifted away from its original mission (Coggins, 2009). Adjudication was intended as a system to provide an impartial, neutral certification process, independent from the contract administration process, conducted by an adjudicator acting as a certifier (Davenport, 2007 & Uher and Brand, 2007). However, due to considerable judicial intervention, adjudication is now subject to the rules of natural justice, (which are applicable in litigation and arbitration),³ and adjudication determinations are amenable to judicial review.⁴ The courts have also allowed damages claims to be included in progress payment claims, which clearly was not the legislation's intent (Davenport, 2007). This somewhat broad interpretation by the courts creates severe repercussions for the NSW adjudication regime, as it was not designed to assess such claims.

A proposal has since been made by a leading adjudicator in New South Wales to have a dual process of adjudication (Davenport, 2007 & Brand and Davenport, 2010). In essence, a dual process of adjudication combines both the strengths of the NSW and UK adjudication regimes. This process works on the idea that the UK adjudication regime is effective in dealing with damages claims, and that the NSW adjudication regime is

¹ In the second reading of the Bill on 8 September 1999.

² See the definitions of 'Progress Payment' under Section 4 of the NSW Act.

³ See *Musico v. Davenport* [2003] NSWSC 977.

⁴ See *Chase Oyster Bar v Hamo Industries Pty Limited* [2010] NSWCA 190.

effective in dealing with certification claims. There will be two different schemes in adjudication. The first scheme will be similar to the one currently provided under the amended NSW Act, except that its scope is restricted to certification claims (excluding damages claims) made by the claimant. The second scheme will deal exclusively with damages claims made by either the claimant or the respondent. Each scheme will have different time frames for responding to a claim and making an adjudication determination. This proposal should be distinguished from another proposal of harmonising Security of Payment (SOP) legislation in Australia, which is in essence the amalgamation of the east coast and west coast models (Coggins, et. al, 2010). This means that there will be a single scheme incorporating both the strengths of the two models.

The amended (2002) NSW Act was amended again on 29th November 2010 and came into force on 28th February 2011. The amendment deals only with the additional right given to the claimant subcontractor to ask the principal to freeze money due to the respondent contractor. The perceived problems with the NSW statutory adjudication regime were not addressed in the Building and Construction Industry Security of Payment Amendment Act 2010 (the new NSW Act). Accordingly, the aim of this paper is to identify the operational problems of the NSW regime from neutral (adjudicators) and user (legal representatives in adjudication) viewpoints. It also establishes potential improvements to the current regime. When the data for this research paper was collected in July 2010, the new NSW Act had not been passed, therefore, the interview questions were structured to ask the respondents about the operational problems of the Act and potential improvements to the NSW adjudication regime. Since the new NSW Act is now in force, the potential improvements to the NSW adjudication regime proposed in this paper may be regarded as missed opportunities instead.

2 Methods

A socio-legal approach was adopted for this study. The first stage involved the review of the relevant literature, parliamentary speeches and consultation documents, cases on statutory adjudication and expert commentaries. It was followed by qualitative interviews with five leading adjudicators and six construction lawyers who represent employers (n=3) and contractors (n=3) in adjudication. This study chose a purposive sampling method to identify interviewees in New South Wales. Using this sampling method, individuals are selected because they have specific experiences central to the phenomenon or because they conform to the criteria set by the researcher. The interviewees in this study had to meet one of a set of strict criteria. They must be:

A senior adjudicator from one of various backgrounds (construction professionals, i.e., architects, engineers and surveyors and construction lawyers) who has been appointed as an adjudicator for at least five cases and must have made determinations on those cases.;

A senior construction lawyer who has represented claimants or respondents in adjudications or court cases involving adjudication matters for at least five cases; or

A senior legal advisor to a contractor, consultant, subcontractor, supplier organisation or group, who has substantial knowledge in adjudication matters.

The reason why the number five (cases) was considered sufficient was that the interviewees would have substantial knowledge on the practice and procedure of adjudication particularly on the difficulties associated with it and potential improvements to the regime. Adjudicators are considered the neutrals in the adjudication process. The *neutral* signifies the third party appointed by the disputing parties to resolve a dispute (Sai-on Cheung et. al, 2002). To obtain holistic views on the issues investigated, this study also included the users of adjudication. Due to the complexity of this study, the *users* should have specialist knowledge on the scope, law, practice and procedure of adjudication. In this regard, the user category should exclude contractors, consultants, subcontractors and suppliers who have been involved in adjudications. Rather, users should include construction lawyers who have represented them in adjudications.

Whenever possible, face-to-face interviews were conducted with the interviewees. This was possible as the author was in Sydney from the 18th to the 24th of July 2010. However, out of 11 interviewees, three were interviewed by phone when the author was back in the UK. Each interview was taped with the consent of the interviewee and then transcribed. The transcripts of the interviews were sent to the interviewees for confirmation. The interview data were analysed using thematic analysis.

3 Operational Problems in the NSW Regime

3.1 Inconsistent Judicial Interpretations

The operation of statutory adjudication in New South Wales has been subject to a great deal of judicial interpretations since its inception in 1999. Unfortunately, there has been apparent inconsistency in judicial interpretations concerning a number of important issues. A leading construction lawyer in New South Wales revealed that:

[S]o far as challenging adjudication determinations well in New South Wales what we have noticed is a bit of an exploration of how that should be done for the first few years of the Act, then the law became fairly settled and just recently in New South Wales the Court of Appeal has actually said well, it's got to all change again so we have gone back full circle. So it's constantly evolving it's not static, difficult to know where a person actually stands in so far as their rights, both under the contract and where the contract fits in, together with the Act.¹

These conflicting judicial interpretations have resulted in a flood of jurisdictional challenges in New South Wales. Parties who have lost their adjudications (mostly employers) may exploit these opportunities to challenge an adjudicator's determination, with the hope to delay or avoid payment to the winning parties. It can be seen from the case law covered in a later part of this paper that the courts' attitude toward enforcement of adjudication decisions in New South Wales differs considerably from its UK counterparts. Whilst the courts in the UK are more vigorous in enforcing adjudication decisions, the courts in New South Wales are more robust in setting aside adjudication determinations.

¹ Construction Lawyers/NSW/Contractors/9.

The crux of judicial inconsistency in New South Wales appears to be caused by the uncertainty of the legal nature of adjudication as interpreted by the courts (either it is intended to be a quasi-judicial dispute resolution method or a neutral certification process). Several judges in New South Wales seem to have perceived adjudication as a quasi-judicial dispute resolution method, rather than a neutral certification process. Notably, McDougall J, who is one of the Supreme Court Judges in New South Wales and has been responsible in many adjudication-related court cases, regards adjudication as a decision making tribunal (McDougall, 2009).

This is contrary to the statement made by Mr. Morris Iemma, the then Minister for Public Works and Services of New South Wales, in the second reading speech of the Building and Construction Industry Security of Payment Amendment Bill 2002 when he said :

Parliament intended that a progress payment, on account, should be made promptly and that any disputes over the amount finally due should be decided separately. The final determination could be by a court or by an agreed alternative dispute resolution procedure. But meanwhile the claimant's entitlement, if in dispute, would be decided on an interim basis by an adjudicator, and that interim entitlement would be paid.

As can be deduced from the above statement, statutory adjudication imposed by the NSW Act is merely a neutral certification scheme (Davenport, 2007 & Uher and Brand, 2007). Three interviewees (all of whom are adjudicators) affirmed that the Government intended adjudication to operate a neutral certification process. An adjudicator with considerable adjudication experience emphasised that adjudication is 'supposed to be a certification process in New South Wales at least, but that is not how it's panned out. It's a quasi judicial.'¹

Five interviewees (four construction lawyers and one adjudicator) although did not specifically mention that adjudication is essentially a neutral certification process support the view that only progress payment disputes should be subject to adjudication and therefore imply that adjudication is a neutral certification process. A senior adjudicator explained:

[T]he preferable model is...a model that ensures that small contractors and subcontractors, have a mechanism for being paid, and the model would be that it looked only at progress payment claims and that is no claims for damages, no claims for time related costs or damages, and it simply meant that if somebody was not getting paid, they could get an assessment.²

The effect of the misconception of the intended nature of adjudication by the courts is three-fold. First, adjudicators' determinations (similar to court judgements or arbitrators' awards) are amenable to judicial review.³ Second, statutory adjudication is

¹ Adjudicator/NSW/Construction Management/3.

² Adjudicator/NSW/Legal/2.

³ The courts initially held that, in a string of cases (*Abacus Funds Management v. Davenport* [2003] NSWSC 1027; *Brodyn Pty. Limited v. Davenport* [2003] NSWSC 1019; *Multiplex Constructions Pty. Limited v. Luikens* [2003] NSWSC 1140; *Transgrid v. Walter Construction Group* [2004] NSWSC 21, *John Holland v Cardno MBK* [2004] NSWSC 258 and *Emergency Services Superannuation Board v Davenport* [2004] NSWSC 697), that adjudication determinations were subject to judicial review. That decision was overturned a year later by the Court of Appeal in *Brodyn v Davenport*³,

subject to the rules of natural justice (which are applicable in litigation and arbitration proceedings).¹ Third, the scope of adjudication has been widened to include damages claims.²

The examination of caselaw discovers that the inconsistency in judicial analysis by the courts, had created a practice amongst dissatisfied claimants to refer a payment claim for the same work that is identical or nearly identical to the one that was earlier referred to adjudication for the second or even the third time, until a favourable determination is achieved. This practice is known in New South Wales industry parlance as *adjudicator shopping*. Three interviewees (two construction lawyers and one adjudicator affirmed the existence of such a practice in the past. One of them stated: ‘Adjudicator shopping...has been a big issue...there are provisions in the Act that deal with that...but the court has made it very clear now that, once the adjudicator has dealt with the issue, then it would be an abuse of process to allow that issue to be re-agitated.’³

The first case in New South Wales that gave rise to the practice of adjudicator shopping was *Rothnere v Quasar*.⁴ In that case, McDougall J held that the submission of a second claim identical to the first claim to another adjudicator did not offend the provisions of the NSW Act and was therefore acceptable. Later, in *John Goss v Leighton Contractors*,⁵ the same learned judge was asked to determine whether the subsequent adjudicator was bound by Section 22(4) of the NSW Act to follow the decision of the first adjudicator. In that case, the first adjudicator decided that the failure on the part of the claimant to comply with Clause 45 in the contract—concerned with the issue of notice of the claim in the prescribed time, manner, and form to the respondent for claims over and above the contract amount—barred its entitlement under the contract. In that case, the first adjudicator decided that the claimant was not entitled to payment for the delay and disruption claims. The second adjudicator was of the view that he was bound by Section 22(4) of the NSW Act and, therefore, followed the decision of the first adjudicator in deciding that the claimant was not entitled to additional money. He refused to follow the ruling in *Rothnere* because of its contradiction with the principle of issue estoppel. McDougall J later set aside the second adjudicator’s determination and reiterated that a claimant can make a further adjudication application for the same claims that have been decided and rejected in earlier adjudication decisions.

The effects of these two decisions led the flourishing practice of adjudicator shopping in New South Wales (Davenport, 2010). Claimants had more than one chance to submit a claim and would continue to do so until favourable determinations were achieved. This practice created a scope for potential injustice to respondents, who may be faced with one adjudication case after another, on the same work that had been previously decided in their favour. The NSW Court of Appeal found this practice unacceptable in *Dualcorp v Remo Constructions*,⁶ when it acknowledged that the principle of issue estoppel is

where the judges held that adjudication determinations were not amenable to judicial review. *Brodyn* was law for almost six years until the recent decision in the *Chase Oyster Bar v Hamo Industries Pty Limited* [2010] NSWCA 190 reverted back to the old position that adjudication determinations are subject to judicial review.

¹ *Musico v. Davenport* [2003] NSWSC 977.

³ (Adjudicator/NSW/Construction Management/3).

⁴ [2006] NSWSC 798.

⁵ [2006] NSWSC 798.

⁶ [2009] NSWSC 69.

applicable in adjudication determinations made under the NSW Act. Once an entitlement to a payment or a decision as to the value of construction work has been determined by one adjudicator, the decision is binding on any subsequent adjudicators.

3.2 Variability in the Quality of Adjudicators

There has been concern raised by the interviewees on the quality of the adjudicators in New South Wales. These interviewees are generally construction lawyers who predominantly represent employers or contractors. Generally, the construction lawyer interviewees are not satisfied with the quality of the adjudicators in New South Wales. An interviewee, who has done more than 120 adjudication cases as a legal representative to employers predominantly, discovered that there is ‘variability in experience and expertise of adjudicators.’¹ Similarly another interviewee who has done more than 100 adjudications as a construction lawyer representing contractors predominantly stated that ‘we have got a lot of adjudicators in New South Wales...of different grades and qualities.’² These interviewees provide valuable insights on the quality of the adjudicators in New South Wales. They are in an ideal position to assess the quality of the adjudicators across the board since they have represented parties in a substantial number of adjudications as legal representatives.

The analysis of the interview data discovers two factors which may contribute to the variability in quality of the adjudicators in New South Wales. First, the variability in quality of the Authorised Nominating Authorities (ANAs).³ Second, the extension of the NSW adjudication regime to include damages claims.

3.2.1 Variability in Quality of the Authorised Nominating Authorities

At present, there are nine ANAs responsible for the nomination of adjudicators under the NSW Act. These ANAs are comprised of professional bodies,⁴ contractor organisations⁵ and private companies.⁶ In the absence of prescribed qualifications and experience applied to adjudicators in the NSW Act, the minimum qualifications and experience standards of adjudicators are set by these ANAs, which are responsible for recruiting adjudicators to serve on their panels. Three interviewees (one construction lawyer and two adjudicators) perceived that the quality of the ANAs in New South Wales is varied. One of them pointed out that ‘not all of the ANAs are the same, [and] not all of the ANAs have that same quality control over adjudicators.’⁷

Some interviewees observed that the selection process undertaken by ANAs in recruiting prospective adjudicators is varied.⁸ Some ANAs specify high requirements

¹ Construction Lawyer/Employers/7.

² Construction Lawyer/Contractors/9.

³ As pointed out by one interviewee: ‘The quality of the adjudicators comes down to the quality of the ANA’, Adjudicator/Construction Management/3.

⁴ Institute of Arbitrators and Mediators Australia, LEADR – Association of Dispute Resolvers and Royal Institution of Chartered Surveyors Dispute Resolution Service (RICS DSR).

⁵ Air Conditioning and Mechanical Contractors Association of NSW Limited, Master Builders Association of NSW Pty Limited and Master Plumbers Association of NSW.

⁶ Able Adjudication Pty Limited, Adjudicate Today Pty Ltd and Australian Solutions Pty Limited.

⁷ Construction Lawyer/NSW/Employers/6.

⁸ For example one interviewee highlighted that ‘The ANAs are varied I guess in their approach to adjudication in a number of ways. One of those may be the emphasis their place on training for example. What kind of selection process they go through to, to put the people on to their panel.’ Adjudicator/NSW/Construction Management/3.

for prospective adjudicators to serve on their panels, whilst others stipulate less extensive requirements. The amount of training provided to prospective adjudicators by ANAs is also varied. Some ANAs provide months¹ of training while others provide mere days of training.² The quality of monitoring of adjudicators on the panels also differs.³ Certain ANAs provide mentoring⁴ and reviewing⁵ systems, whilst others do not. Some ANAs are also perceived to have a reputation of being claimant-friendly.⁶

The problem of variability in quality of adjudicators among ANAs could be caused by several factors. The absence of specific provisions in the NSW Act regarding qualifications and experience of adjudicators may be a contributing factor. Each ANA imposes a varying set of selection criteria for the recruitment of adjudicators, and some ANAs impose stricter requirements than others. The absence of an adjudication registry, similar to that established in Queensland, that nominates training organisations responsible for delivering courses in accordance to an approved syllabus may also be a factor contributing to varying quality of adjudicators across the ANAs. The registration of an adjudicator under the NSW Act should be standardised so that the exact requirements in terms of qualification and experience can be set at a higher standard across all the ANAs.

3.2.2 *The Extension of Adjudication to include Damages Claims*

It may be argued that the extension of the scope of application of adjudication to include damages claims may have caused the varying quality of adjudicators in New South Wales. Damages claims, which usually involve complex analysis of the law, are arguably unsuitable for the NSW adjudication regime, which is designed as a certification process with a short time frame for the adjudicator to make a determination (Davenport, 2007). As some adjudicators have little or no legal knowledge, this could contribute to the lack of quality of the adjudicators specifically when dealing with damages claims. As pointed out by one interviewee ‘many of the current adjudicators are not legally qualified and they are producing very bizarre and terrible results.’⁷ It is expected that adjudicators with little or no legal knowledge may find it difficult to assess damages claims, particularly on the parties’ entitlements of damages under the law. The entitlement of damages claims involves a complex analysis of culpability and is largely based on the examination of case law. Furthermore, the strict time frame of ten business

¹ As highlighted by one interviewee who is an adjudicator ‘Our training is not two days, it’s three months.’ Adjudicator/NSW/Legal/5.

² As highlighted by one construction lawyer interviewee: ‘[prospective adjudicators] merely have to go through a short course, that course is no longer available, so people who are already qualified are already in and nobody else is being admitted to be an adjudicator.’ Construction Lawyer/NSW/Contractors/8.

³ As highlighted by one interviewee: ‘[T]here is insufficient scrutiny of the adjudicators.’ Adjudicator/NSW/Legal/2.

⁴ One interviewee explained ‘[A]ll adjudicators are in groups, so that if they’re resting an issue, they don’t have to, they are not alone, they can go into the group, and say, I am resting with this issue, has any one encountered with this issue before? This is the way the courts work. That’s how the judges work.’ Adjudicator/NSW/Legal/5.

⁵ As highlighted by an interviewee who is also a senior adjudicator on an ANA’s panel: In the XXX [the name of a nominating body], there is a process whereby every adjudication determination is reviewed...to ensure that the standard is met. Adjudicator/Legal/2.

⁶ As pointed out by a construction lawyer who has done more than 100 adjudications; ‘Some ANAs are very claimant friendly, and so, people tend to go to the most friendly ANA.’ Construction Lawyer/NSW/Contractors/9.

⁷ Construction Lawyer/NSW/Contractors/8.

days to make a determination may add considerable pressure to the adjudicator. These two factors may lead to adjudicators producing erroneous determinations.

3.3 Rubber Stamp Approach

One of the main criticisms of the NSW adjudication regime advanced in the literature is the fact that it allows the claimant to apply for summary judgment on the statutory debt created as a result of the respondent's failure to issue a payment schedule.¹ One respondent expressed this concern when he said: '[I]t's very harsh particularly during the learning cycle of how the Act works for respondents to be unfairly penalised because of ignorance. For example if they don't put on a payment schedule, they might be hit with a payment claim or a judgement for \$2million simply because they didn't know. That is not fair.'² The case of *Walter Construction Group v CPL (Surry Hills)*³ provides a good illustration on the inherent difficulties caused by this so-called rubber-stamp mechanism. In that case, a multi-million dollar payment claim, which included damages claims to the respondent, was issued over Christmas. The respondent later failed to issue a payment schedule. The failure allowed the claimant to recover the claimed amount as a statutory debt in a court of competent jurisdiction by way of summary judgment. The claimant then went into liquidation and the respondent could not recover the overpaid amount. In that case, the claimant made a claim which exceeded the amount to which the claimant was entitled, and there was no option for the claimant to apply for adjudication.

3.4 Accessibility of the NSW Act

A majority of adjudicators and one construction lawyer⁴ indicated that the NSW Act is not being widely used by industry participants. They found that the NSW Act is used by big construction companies, but not small or medium-sized companies. One of the interviewees stated: 'I guess the only difficulty with it is,...it is still not used by such small subcontractors. It is really only the big ones who can afford legal representation probably.'⁵ The finding of the study confirms the study of Brand and Uher (2010), it must be stressed that, the sample size of this qualitative study is small, therefore this finding cannot be generalised to reflect the whole population. The adjudicators and construction lawyers who have been involved in many adjudications between them are in a good position to assess who has been using the NSW Act, as they are appointed by parties to become adjudicators or legal representatives. From their personal experience in adjudication, they found that the NSW Act is not used by all levels of the contractual payment chain, but rather at the top level, i.e., between the employer and the contractor.

This is divergent from the intention of Parliament, as the NSW Act was intended to assist small builders to recover payment for their errant paymasters. The fact that the NSW Act covers oral contracts as well as written contracts exemplifies Parliament's intention to provide cash flow protection to subcontractors, as they normally carry out work based on oral contracts. Therefore, if subcontractors are not using the NSW Act as Parliament intended, it brings the effectiveness of the NSW Act into question.

4 Potential Improvements

4.1 Administrative Improvements

4.1.1 *The Variability in the Quality of Adjudicators in New South Wales*

It is established from the analysis of the interviews that the quality of the adjudicators is effectively determined by the ANAs. From the interviews, it was discovered that some ANAs provide a review system in which adjudicators' determinations are reviewed by a senior adjudicator or a panel of senior adjudicators before being published.¹ Some ANAs have a mentoring system in which a junior adjudicator may discuss the case he or she is currently working on with a senior adjudicator.² Some ANAs have extensive databases that provide information on case law and past adjudicators' determinations.³ Certain ANAs are very efficient in 'picking the right sort of adjudicator for the right sort of dispute'.⁴ In some ANAs, the adjudicators are placed in groups to discuss their adjudication cases.⁵

4.1.2 *Accessibility of the NSW Act*

The issue of the accessibility of the NSW Act is fundamental, as one of the parameters to measure the effectiveness of Security of Payment legislation is by determining its level of use by industry players (Uher and Brand, 2008). The findings of the interviews reveal that the NSW Act is not widely used by subcontractors – the primary intended beneficiaries of the NSW Act. This is unfortunate, as the NSW Act has been in operation for more than a decade now, yet a large segment of the industry is not using it.

Despite having some of the highest numbers of adjudication applications in Australia (together with Queensland), there is reason to believe that the NSW Act is not widely used by the industry. Since 2005, the number of adjudication applications in New South Wales has levelled out at around 900 applications annually (Coggins, 2009). Queensland, which was the third jurisdiction in Australia to enact SOP legislation, had the highest number of adjudication applications (around 1000) in the period between 2008 and 2009. In the period between 2007 and 2008 the number of adjudication applications in Queensland was around 500. There was almost a 100 percent increase in terms of the number of appointments from the period of 2007-2008 to 2008-2009 in Queensland.

The fact that Queensland has overtaken New South Wales in terms of having the highest number of adjudication applications in Australia offers some interesting observations. Despite Queensland having a population of only 4.53 million compared to 7.25 million

¹ As highlighted by an interviewee who is also a senior adjudicator on an ANA's panel: In the XXX [the name of an ANA], there is a process whereby every adjudication determination is reviewed...to ensure that the standard is met. Adjudicator/NSW/Legal/2.

² As highlighted an interviewee: I'm involved in mentoring of adjudicators. Adjudicator/NSW/Legal/5.

³ As highlighted an interviewee: [The adjudicators] have access to enormous internal resources. Adjudicator/NSW/Legal/5.

⁴ Construction Lawyer/NSW/Employers/6.

⁵ As highlighted by an interviewee: [A]ll adjudicators are in groups, so that if they're resting an issue, they don't have to, they are not alone, they can go into the group, and say, I am resting with this issue, has any one encountered with this issue before? This is the way the courts work. That's how the judges work. Someone might say, yeah, I've dealt with that, when they talk about it, the adjudicator doesn't have to follow it, but the process, the fact that they are talking to people in their group who collectively is a massive amount of experience available. Adjudicator/NSW/Legal/5.

in New South Wales,¹ and less volume of construction activity when compared with New South Wales, based on the recent number of adjudication applications it may be inferred that Queensland has been successful in terms of addressing the issue of accessibility of its SOP legislation. The Queensland version of the Security of Payment legislation closely resembles the NSW's SOP legislation; therefore, the argument that the NSW Act is more complex than its Queensland counterpart in terms of operation, which may have the effect of deterring industry usage, is not attestable. The reason statutory adjudication is widely used in Queensland could be attributed to the measures taken by the government to promote the SOP legislation.

The Queensland government formed the Building and Construction industry agency, a branch of the Building Services Authority, 'to provide the infrastructure to assist the Adjudication Registry, in its duties to give effect to the Building and Construction Industry Payments Act 2004.'² One of the roles of the Adjudication Registry is to 'ensure that an effective educational and awareness strategy is in place with regard to the statutory obligations and entitlements established under the Act.'³ No equivalent agency exists in New South Wales. The agency responsible for matters relating to Security of Payment in New South Wales, is NSW Procurement, a division of the NSW Department of Services, Technology and Administration. The roles of the NSW Procurement are varied and are not solely focused on Security of Payment matters.

It is proposed that an agency whose exclusive role is to look into Security of Payment matters should be established in New South Wales to actively promote accessibility to the NSW Act. Apart from the government, promotion of the NSW Act also falls upon the authorised nominating authorities, professional bodies and trade associations.

4.2 Potential Legislative Improvements to the NSW regime

4.2.1 Dual Process of Adjudication

Four interviewees (three adjudicators and one construction lawyer) support the proposal of introducing a dual process of adjudication. As stated in one interview:

[T]he ideal would be to have, a dual system, allowing the popularity obvious success of the New South Wales model in dealing with payment claims, to allow that to run, parallel to another adjudication system which ultimately connects in the end, that deals with other types of money claims that allows both parties to enter into the arena, and it looks more like an arbitration in a sense.⁴

There are two opposing views expressed by the rest of the interviewees. Four interviewees (comprising of both three construction lawyers and one adjudicator) agreed that adjudication should only be used for progress payment claims. Three interviewees (two construction lawyers and one adjudicator) supported introducing adjudication to a wide spectrum of disputes, but one of them felt that the issue of quality of adjudicators

⁴ Adjudicator/NSW/Construction Management/3.

must be first addressed. The introduction of a dual process of adjudication could fulfil the aspirations of these two diverging groups.

The dual process of adjudication is essentially a hybrid between the UK and New South Wales adjudication schemes. In essence, the dual process of adjudication combines the positive attributes of both the NSW and UK adjudication regimes (Davenport, 2007). This process is based on the idea that the UK adjudication regime is effective in dealing with damages claims but deficient in dealing with certification claims, while the NSW adjudication regime is effective in dealing with certification claims but deficient in dealing with damages claims. Interestingly, the limitations and the strengths of these two adjudication schemes do not overlap; hence, an integration of these schemes could offset the weaknesses inherent within one scheme by adopting the strengths of the other.

There are two different scheme for a dual process of adjudication. The first is similar to the system currently provided under the amended NSW Act, except that its scope would be restricted to certification claims made by the claimant. The second scheme, which mirrors the UK adjudication regime, would deal exclusively with damages claims made by either the claimant or the respondent.

Each proposed system would have different time frames for responding to a claim and making an adjudication determination. For ease of reference, the term *certification scheme* will be used to refer to the adjudication regime that mirrors a certification process whereas the term *dispute resolution scheme* will be used to refer to the adjudication regime that is akin a quasi-judicial dispute resolution method.

Three interviewees, although they did not specifically mention the dual adjudication process, suggested that there should be different time frames for different disputes. One of them suggested; that there be perhaps slightly different time frames or different processes for different types of disputes.’¹ This suggestion appears to be consistent with the idea of the dual process of adjudication.

The proposal for a dual process of adjudication should be distinguished from another proposal of harmonising Security of Payment legislation in Australia, which is essentially the amalgamation of the east coast and west coast models (Coggins, et. al, 2010). This means that there would be a single scheme incorporating the strengths of both models. The SOP regimes in Western Australian and the Northern Territory, which are closely modelled after the UK regime, are collectively referred to in industry parlance as *the west coast model*, whereas those states and territories in Australia whose SOP regimes are largely based on the NSW regime are together known as *the east coast model*. Some of the interviewees applauded this idea, however, they felt that it may be difficult to realize. As one said: ‘Well I think that is admirable intent but the problem is that you have got two radically different models at the moment.’²

The dual process of adjudication could solve most of the problems identified earlier in this paper. The problems that have emerged as a result of inconsistent judicial analysis may be eliminated by the dual process of adjudication. The certification scheme should not be subject to judicial review and the rules of natural justice, as it is designed to be prescriptive as a result of limited time frames and the claimant’s sole right to initiate

¹ Construction Lawyer/NSW/Employers/7.

² Adjudicator/NSW/Legal/4.

adjudication. There should be an express provision in the NSW Act that gives effect to these exclusions. These may mean that grounds for jurisdictional challenges, which are usually advanced by respondents to resist payment to claimants, would therefore be minimised; this works toward the policy objective of the NSW Act by improving cash flow in the construction industry.

The scope of the certification scheme should also exclude damages claims. In order to distinguish between certification and damages claims one interviewee proposed that: ‘Distinction between what is a damages claim, we’re looking at similar types of words towards the Victorian legislation, which already pull out a lot of the damages claims.’¹ However, the Victorian legislation excludes unapproved variations from being subject to adjudication. Arguably, unapproved variations are not damages claims and therefore should be part of the certification scheme. Conversely, delay and disruption claims arising from variations either approved or otherwise should be excluded from the certification scheme, as they are essentially damages claims. The inclusion of unapproved variations within the scope of the certification scheme may enliven the practice of ambush claims. Nonetheless, the severity of these ambush claims may be minimised if a time bar provision is introduced in the Security of Payment legislation.

An example of this time bar provision can be found in the Victorian Act. The Victorian Act provides that a period of 3 months after the reference date referred to in Section 9(2) is the minimum period for a claimant to make a claim (either a monthly, one-off or final payment claim). It also Act provides freedom to the parties to agree to a longer period for the claimant to make a claim, but to do so is to the detriment to the respondent, who may be faced with ambush claims if the claimant has a longer time to make a payment claim.

The exclusion of damages claims from the ambit of the certification scheme may eliminate the problems of ambush, limited time frame for the respondent to respond to a payment schedule and adjudication application, and limited time frame for the adjudicator to make a determination. Since ambush tactics are more common in damages claims, the distinction made by the dual process of adjudication may eliminate or at least diminish the risk ambush in the certification scheme. If the risk of ambush claims were minimised, the respondent and the adjudicator might no longer be faced with time pressure to perform their duties as prescribed in the SOP legislation.

The dispute resolution scheme that the dual process introduces should be subject to judicial review and the rules of natural justice. There should be an express provision in the NSW Act to this effect. Since the dispute resolution scheme performs a quasi-judicial function, it is acceptable that adjudication determinations made under this scheme should be subject to judicial review and some of the rules of natural justice. The problem created by the courts in extending the application of the NSW adjudication regime to include damages claims may also be solved, as the dispute resolution scheme provides longer time frames for the respondent and the adjudicator to perform their duties under the SOP legislation, and allows both parties in the contract to initiate adjudication. The problem with ambush claims may also be minimised if the dispute resolution scheme adopts the time bar provision as proposed in the certification scheme.

¹ Adjudicator/NSW/Legal/5.

4.2.2 *Administration of Authorised Nominating Authorities and Adjudicators by the Adjudication Registry in the NSW Act.*

As explained earlier, in New South Wales the quality of the Authorised Nominating Authorities is varied. This leads to a varying quality of adjudicators. The problem lies in a lack of monitoring on the part of the ANAs. For example, the absence of specific provisions in the NSW Act about qualifications and experience of adjudicators, means that ANAs are at liberty to specify any selection criteria; this may lead to the variability of quality among adjudicators.

In Queensland there is a body that closely monitors the conduct of the ANAs and the adjudicators. The Adjudication Registry, a body created by the Queensland Act consisting of a Registrar and other staff, has functions of registering adjudicators and ANAs, publishing adjudicators' determination and collecting statistical data.¹ The administration of the ANAs and Adjudicators by the Adjudication Registry is spelled out in detail in the Queensland Act. The requirements imposed on the ANAs in recruiting adjudicators are consistent as prescribed in the Queensland Act. As a result, the ANAs all apply the same set of selection criteria in recruiting their adjudicators. This leads to consistency in terms of quality of adjudicators. It is proposed that in order to have consistency in the quality of adjudicators, the approach taken by the Queensland Government in spelling out the administrative matters of the ANAs and the qualifications of adjudicators in the body of SOP legislation should be introduced.

5 Conclusion

It is evident that the NSW Adjudication regime has been effective thus far in improving payment practices. However, there remain problems areas which need to be addressed. The guidance from courts so far has been inconsistent. Inconsistent courts' interpretations lead to jurisdictional challenges. This is to contrary to the objective of Parliament that adjudication should be subject to minimum court involvement. It is apparent from this study that the quality of the adjudicators in New South Wales is varied amongst the ANAs. The rubber stamp approach is also perceived as one of the main deficiencies of the NSW regime. The fact that adjudication is not widely utilised by subcontractors is also a major issue of concern. The introduction of a dual process of adjudication could solve most of the problems identified above. As to the quality of adjudicators, the ANAs should be more rigorous in recruiting their adjudicators by imposing stricter selection criteria. It is important that the quality of the adjudicators in these ANAs should be sustained and improved upon by having the mechanisms discussed earlier in this paper. The introduction of an adjudication registry that is entrusted with the task to actively promote adjudication should address the issue of accessibility of the NSW Act. This governing agency should also monitor the conduct of the ANAs.

Abstract:

This paper provides an insight into the factors which impact upon the selection of dispute resolution methods for commercial construction in the Melbourne industry. The ten factors used are cost, speed, outcome, enforceability, privacy and confidentiality, open and fairness, control, flexibility creative remedies and relationships. The dispute review board will be compared with alternative dispute resolution methods to demonstrate the differences and the impact it has on construction performance, primarily time, cost and quality. Through questionnaire survey, the relative importance of these factors in the selection of dispute resolution methods is examined and through interviews, the efficiency of the current alternative dispute resolution methods operating in Melbourne is compared with the efficiency of the dispute review board. Concerns regarding the use of DRB arising from high costs, lack of faith in the board's ability to achieve qualities of neutrality and impartiality in the selection of board members as well as the general attitude of resistance to change in the highly adversarial culture of the construction industry will be discussed. Negotiation is still the preferred method of dispute resolution in Melbourne.

Keywords:

dispute review board, alternative dispute resolution, Melbourne construction industry

1 Introduction

Construction is a highly complex activity filled with uncertainties: economical, financial, and physical risks, as well as scope variations and documentation complexities (She, 2010). Research of the past indicates that during the construction process these risks can lead to disputes arising between two or more of the parties

involved in the works (Goldfayl, 2004). In Australia, 50% of all projects over 500 million are delayed (Dawson, 2007).

The key requirements of any methods of dispute resolution are they must be based on justice and is fair and impartial (Goldfayl, 2004). Construction law in Australia is based the common law. For litigation, it is based on the adversary system consisting of a series of statements of facts and arguments of law put forward by the party to be disputed and challenged by the other party (McGranaghan, 1992). For other dispute resolution methods such as the Alternative Dispute Resolution (ADR) it is non-binding however when a written agreement has been concluded between the two parties then it becomes a contract which both parties are obliged to comply.

The Dispute Review Board (DRB or DB) is a Dispute Avoidance Procedure method to settle various construction dispute claims (Gerber, 2001). Other techniques include voluntary negotiations between the parties; third party assisted negotiations such as mediation, conciliation and adjudication; and adversarial approaches such as arbitration or litigation (Sprague, 2006). The Melbourne construction industry is based more on relationships than most others and as a result dispute resolution using ADR methods, such as mediation allow flexibility in addressing technical issues and preservation of relationships as well as minimising adverse publicity (Sprague, 2006) (Megens, 2005). However, sufficient attention should be directed to the dispute resolution clauses at the time of contract preparation and negotiation to avoid costly, time consuming as well as distracting and ineffective dispute resolution processes later on. (Gould, 2006).

This research aims to explore the importance of the factors which affect the selection of dispute resolution methods in Melbourne when compared to the dispute review board as well as the efficiency of the current dispute resolution methods in Melbourne

2 Conflict and Dispute

Conceptually a *conflict* is a difference between two or more beliefs, ideas, or interests (Collin et al. 1996). Based on the above definition conflict in construction may include dissatisfaction, disagreements over contract administrator's decisions, anger, hostility, and negative attitudinal propensities by parties (Aibinu *et al* 2008).

2.1 Disputes- When conflicts are unresolved

Dispute arises in a situation when a claim or assertion made by one party is rejected by another party and this rejection is not accepted (Kumaraswamy, 1998). A claim is an assertion of a right to money, and property, or a remedy and can be made under the contract itself, for breach of the contract, or for breach of a duty in common law (Powell-Smith and Stephenson, 1989). Construction claims can be in the form of money and time claims by the main contractor against the project owner for extension of contract time and additional payment arising from a specified event in the contract (Aibinu *et al* 2008). The claim can be any application to the project management team pursuant to any relevant clause of the contract including any variation to payments, extension of time and or damages for any alleged breach of duty by the employer or employer's management team (Kumaraswamy, 1998).

3 Dispute Resolution Methods

The common dispute resolution methods operating in Melbourne are litigation, arbitration, mediation, conciliation, adjudication, mini-trials, facilitated negotiation, partnering and expert determination.

3.1 Litigation

Litigation is a legal proceeding in a court or a judicial context to determine and enforce legal rights (Hill, 2008). This is the least preferred method in the construction industry as the courts act on the adversary system (Bailey, 1998) and damage business relationships (Sprague, 2006). Besides the slow, expensive, time consuming, risky and stressful procedure which litigation brings, there is no real certainty of results other than a certainty of at least one loser (Merritt, 2006).

3.2 Arbitration

Arbitration is a mini-trial for a law suit ready to go to trial, held in an attempt to avoid a trial and is conducted by an independent person, usually with some relevant skill or knowledge, to determine the dispute (Bailey, 1998). During the arbitration process, parties make submission to an arbitrator and are bound by the arbitrator's decision (ACDC, 2005).

3.3 Mediation

Mediation is a prominent ADR method used in the Melbourne construction industry and is now a firmly established preferred dispute resolution tool for construction claims (Megens, 2005). Mediation is an attempt to settle a legal dispute through an active participation of a third party, a mediator, who works to find points of agreements and make those in conflict agree on a fair result (Hill, 2008). Resolution is attempted but settlement is not always achieved (Hill, 2008).

3.4 Conciliation

Conciliation is similar to mediation however the main goal is to conciliate by seeking concessions.

3.5 Adjudication/Security of Payment

Adjudication is the process where an independent person, the adjudicator, makes a determination as to the amount, if any, which the respondent owes to the claimant, on a specific date it was (or will be due) to be paid and on what interest applicable (IAMA, 2006). The objective is to impose a settlement on parties.

3.6 Mini-Trials

Mini-trials are a structured information exchange attended by representatives authorised to settle the dispute and are used where a dispute exists between the key decision makers of both parties (Sprague, 2006).

3.7 Facilitated Negotiation

Facilitated negotiation involves an independent and objective person which enters the negotiation session to assist the parties in reaching agreement (Berman, 1995). The

purpose is to facilitate a mutual understanding of both parties rather than settlement (Sprague, 2006).

3.8 Expert Determination/Appraisal

Expert determination is a person who a specialist in a technical subject who may present his or her expert opinion without having been a witness to any occurrence relating to the lawsuit or criminal case (Hill, 2008). The critical areas of importance for the 'expert' are to remain independent of, and act fairly and impartially between parties and to adopt a suitable procedure whilst avoiding unnecessary delay and expense in the given circumstances (Sprague, 2006).

3.9 Partnering in Alliance Contracting- towards proactive dispute avoidance

Partnering is a project procurement method where the parties to the contract share a common goal aim to complete the project successfully (Sprague, 2006). This is achieved by sharing both the benefits and risks of the project. Partnering is a proactive dispute avoidance technique. It is based on relationships and trust that all parties share a common goal (Eilenberg, 1996). Under this procurement method, a contract is set up with an agreed target price and incentives for parties.

4 Factors which impact upon the selection of dispute resolution methods

Many researchers and practitioners have investigated the attributes of ADR methods. York (1996) was concerned with the practical issues and identified time, cost and preservation of relationships, enforceability, degree of control by parties, flexibility in procedure and confidentiality as factors which had an impact upon the selection of dispute resolution methods (Cheung *et al* 2002). David (1988) focused on social and human issues such as impartiality, consensus, and continuing business relationships (Cheung *et al* 2002).

Cheung *et al* (2002) has identified ten criteria as the most common factors which affect the performance and selection of dispute resolution methods. These are:

4.1 Cost

The costs associated with dispute resolution involve reaching settlement agreements including expenses relating to revenue, the neutral third party fee, documentation, and settlement costs.

Cost is the one of the most critical criteria for organisation when assessing which dispute resolution method to use for dispute resolution as it affects the profit share of the project outcome. In assessing the suitability of a case for ADR, a cost-benefit analysis of the costs and value of the case must be undertaken. This involves trading off the various criteria and also helps the parties to better understand the issues involved and the expense likely to be incurred if the dispute continues.(Cheung *et al* 2002).

4.2 Openness, Neutrality and Fairness

Neutrality and fairness depend heavily on the competence, training, and integrity of the neutral third parties. During the resolution process, a neutral third party owes a duty of

care to his or her clients to remain impartial. He or she facilitates the parties' reaching a settlement but must make a conscientious effort to avoid personal biases. The neutral third must not have any professional or financial relationship with any party otherwise the information must be disclosed to the other party. Finally the neutral third party must be agreed by both sides. Since the choice of the neutral third party is of paramount importance there must be a code of conduct to monitor the standard of professional mediators, conciliators and arbitrators. This will enhance the trust and comfort level between parties to voluntarily reach a settlement.

4.3 Speed

Time is money in the world of business and project management. Lengthy delay of dispute resolution will delay the progress of works resulting in extra costs and incur potential penalty points.

4.4 Outcome

The outcome of a construction dispute is usually related to the costs liability. The party which initiates the dispute feels that the other party owe costs for reasons such as variation of payments, quality of workmanship, and final payments or owes compensation costs due to factors such as delay of works, payment for extension of time and liquidated damages.

4.5 Privacy and Confidentiality

Confidentiality is an implied and inherent feature of ADR processes that parties to a dispute are not allowed to disclose any information or materials to the public unless by mutual consent of the parties.

4.6 Enforceability

ADR methods of dispute resolution are non-binding therefore it cannot be enforced upon by the courts unless a written agreement is concluded. However, the selection of a competent neutral facilitator with excellent negotiation skills can encourage the parties to settle.

4.7 Preservation of Relationships

A continuing relationship is one of the key elements for any organization to strive for. A good relationship is always based on trust, common interests, and respect and requires the effort and commitment of the parties to make it last. ADR methods allow parties to negotiate the process of dispute resolution and the neutral facilitator assists both parties to always focus on the issue of the dispute and to try to achieve a win-win situation which is crucial to the Melbourne construction industry as it is heavily reliant on relationships (Sprague, 2006).

4.8 Flexibility

The non-binding nature of ADR methods is likely to encourage cooperation for all parties to reach an agreement through negotiation as it is more flexible than traditional methods.

4.9 Creative Remedies

Creative agreement is directly related to the skills, experience, and inherent character of a neutral third party. Depending on the nature and requirements of the parties, he or she should try to come up with a solution that can satisfy both parties' needs. Settlements can include human factors such as business relationships and personal issues can be considered. Lateral thinking by the facilitator is vital as it takes the various factors into consideration before reaching a settlement. Reality testing by writing down the pros and cons of each possible outcome will allow parties to feel fully informed with the decision making power in their hands.

4.10 Degree of Control

When parties feel in control of the outcome and processes involved to reach an agreement, it will also mitigate the adversarial climate between disputing parties.

5 Dispute Review Board-Overview of the structure, components and use

The Dispute Review Board (DRB) consists of three *qualified* members committee, nominated by *both parties*, formed at the *start of the project* and meet periodically *on site* to discuss issues (DRBF, 2007). Then they form non-binding recommendations. If the parties are *unsatisfied*, they can turn to other methods of binding or non-binding methods of such as mediation and conciliation or any other ADR methods (DRFB, 2007).

5.1 Selecting, nominating and appointing Board Members

The three members nominated by both parties (Gould, 2006) :

They must not have any financial ties to any party either directly or indirectly involved in the contract, not be currently employed by any party directly or indirectly in respect of the contract, and

Not have a close professional or personal relationship with a key member of any party directly or indirectly involved in the contract that could give rise to the perception of bias

Each party selects one member which is approved by the other party and then a third member is chosen by the two selected members. The three DRB members then selects one as the chair with the approval of both the contractor and the owner.

Members must be qualified in both the technical and legal facets of construction practices and methods.

5.2 Formation of DRB clause into the contract at the commencement of the project (Gaitskill, 2005):

When DRB is established before the commencement of the project, the members will have the relevant design documentations, specifications and project scope as well as understanding the contract conditions.

5.3 Periodic visits on site to resolve issues (Gaitskell, 2005):

Meeting 3 to 4 times a year or more frequently as agreed by both parties

Issues are seen, heard and resolved as they arise on site.

5.4 Issuing non-binding recommendations (Gaitskell, 2005):

DRB can act as a flexible and informal advisory panel. Before issuing a recommendation, the DRB may be asked for general advice on any particular matter. The DRB would then look at documents and or visit the site as appropriate and most usually, provide an informal oral recommendation, which the parties may choose to adopt.

If the parties were not satisfied, the DRB would follow the formal procedure of exchange of documents and a hearing and afterwards issue a formal written recommendation.

The decisions made by the board are non-binding but are generally accepted by the parties due to the merit of the expert opinion been admissible of the matter proceeds to arbitration or litigation.

5.5 Costs associated to implement the Dispute Review Board (DRBF, 2007):

The fees will be shared by both parties.

The fees will range between 0.05%- 0.25% of the project value and will act as an insurance premium against potential hefty dispute costs if the claim progresses to litigation and arbitration.

6 Analysis of how the DRB should perform with the ten factors which impact upon the performance and selection of Dispute Resolution Methods

Ten factors were used to test the performance and selection of dispute resolution methods namely, cost, speed, outcome, enforceability, privacy and confidentiality, open and fairness, control, flexibility, creative remedies and relationships as identified by Cheung *et al*, (2002).

6.1 Cost

The direct fees for the DRB ranging from 0.05% to 0.25% of the total construction cost. The fees are shared by both parties which mitigate the conflict of interest and perception of bias that *all three* DRB members will take one particular side. In mediation, conciliation and other current ADR methods operating in Melbourne, there is only *one* member facilitating the negotiation for settlement between two parties.

6.2 Openness, Neutrality and Fairness

Neutrality, openness and fairness are the core values of the DRB. The board members must not have financial ties with any party. If there is a conflict of interest, it must be disclosed to all parties. The selection process for the DRB members is a consensus approach.

6.3 Speed

The DRB is established before the commencement of the project. It will involve the experts every early on the project and potential claims dispute may be identified *before* the issues surfaces as the conflict is resolved as they arise *on site* where as the current ADR methods in Melbourne resolve disputes *after* the event has occurred. This solves the problem of delaying the time to sort out missing documentation and historical information to make an accurate determination. Additionally, the periodic site visit will improve the adversarial nature between conflicting parties when liability can be determined before the conflict turns into a dispute.

6.4 Outcome

The DRB has the flexibility of acting as an advisor as well as issue non-binding recommendations. The use of lawyers on the board is discouraged to avoid an adversarial climate however the question of liability is ruled upon by *three* members. This should encourage the parties to accept the board decisions especially if the contract language includes a provision for the admissibility of a DRB recommendation into any subsequent arbitration or legal proceeding.

6.5 Privacy and Confidentiality

The code of ethics for DRB stipulates that the DRB must keep all information arising from the DRB review and hearing confidential and since the dispute is resolved on site, no external party will know that an issue exists. This should preserve business relationships and prevent any unnecessary complexity which may arise from external parties after hearing about the dispute.

6.6 Enforceability

The DRB is non-binding however, the goal of the DRB is facilitate the conflicting parties to resolve their differences so that construction works can continue on site.

6.7 Preservation of Relationships

Both parties agree on the selection of the DRB members at the appointment of the board. This means that all parties are willing to cooperate with each other in good faith and trust the board's decision making abilities when a conflict arises. If the parties are unsatisfied with the decisions of the DRB, they are free to sort dispute resolution methods.

6.8 Flexibility

The DRB can act as a flexible panel acting as an advisor which will facilitate the negotiation process more than the current ADR methods which can only act as a neutral facilitator as with mediation or act to make a judgement of a technical issue as with expert determination. Litigation and arbitration are the least flexible methods as it is only interested in the issue which relate to a point of law and does not take into account of any other factors.

6.9 Creative Remedies

The DRB is a panel of three experts with different but relevant qualifications, skills and more than ten years of experience within the construction industry. The blend of

qualifications and experience of the three-person DRB can provide a powerful combination of decision-making abilities than one person trying to make a judge within their limits of understanding and experience which is the case with expert determination.

6.10 Degree of Control

As mentioned before, the DRB members are agreed upon by both parties and the board resolves issues on site. The board can also act as an advisory panel which is not possible with the current operation of ADR methods. These factors give both parties a feeling of being control of the outcome and processes involved to reach an agreement.

7 Methodology

The entire process comprised of a pre-interview questionnaire, structured interview and a post interview questionnaire to examine the respondents' perception of the DRB's conflict management mechanisms in comparison with other dispute resolution methods.

Pre-interview questionnaire: The respondents were asked to comment on their experience with the current dispute resolution methods operating in Melbourne as well as the efficiency of the methods.

Interview Questions: and then they were asked to read some information regarding the use of DRB and they were asked questions regarding their perception of the DRB as well as any concerns regarding the implementation of the mechanism in the Melbourne construction industry.

Questionnaire: There were eleven survey questions asking the respondents to rank from the likert scale of 1 to 5 (1 for extremely unimportant and 5 for extremely important), whether they think the ten criteria factors are important in the comparison for the selection of dispute resolution methods.

7.1 Population and Sample

The population sample was restricted to the Melbourne industry. The research sample consisted of twenty one respondents which undertook both the structured interview and questionnaires. The research sample included: five architects, three engineers, three quantity surveyors, two development managers, three project managers, one project director, one CEO, one site foreman and two construction managers. Fifteen of these participants had over ten years of experience in their respective field of work. Eighty percent of the respondents answered that the project size their company generally undertake is in excess of \$10 million. The average number of disputes that each building professional had been involved in over the last five years was five which confirms that these respondents have had a reasonable level of experience.

7.2 Data Analysis Tool

7.2.1 Structured Interview Analysis

The structured interview has been analysed using the 'grounded theory' approach, an example can be referred in Strauss and Corbin (1998).

7.2.2 Questionnaire Survey data analysis

To measure the performance of the conflict management mechanisms of the DRB in comparison with other dispute resolution methods a mathematical equation, Relative Importance Index (RPI) was used for the analysis of the quantitative data.

7.2.3 Relative Performance Index

To determine the performance of any dispute resolution method when compared with DRB on each criterion, the respondents' ratings are transformed in Relative Performance Index (RPI) for each criterion. RPI is computed using the following mathematical expression:

$$RPI = \sum W_i / (A \times n)$$

Where $\sum W_i$ is the total score assigned importance of a decision criterion by all the respondents;

A is the highest weight (5; and

n is the number of respondents

The computed RPI are then ranked for each dispute resolution method on each criterion. The areas of comparative advantages of the DRB over dispute resolution method on each criterion were identified.

8 8 Results

8.1 Analysis of Data from Pre-Interview Questionnaires

The results of this section present the demographics of the respondents and the current climate of dispute resolution in the Melbourne construction industry.

8.1.1 Profile of Respondents

Figure 8.1.2 Diverse mix of professionals interviewed for this research.

As shown in figure 8.1.2 48% of the respondents held positions in a managerial capacity and 52% of the respondents held positions as a consultant in design, engineering and cost management. This demonstrates that all the respondents who participated in the research had the capacity of to make decisions regarding dispute resolution in their organisation.

8.1.2 Respondents Age

Figure 8.1.3 Age groups of the respondents who participated in the research.

As shown in figure 8.1.3, 76% of the respondents were over thirty years old. 33% of the respondents were between the age group of 30-40 years old and 29% of the respondents were between 40-50 years old. 14% of the respondents were between the ages 50-60 years and held positions in senior management and 24% of the respondents were between the ages of 25-30 years. Different age groups of professional have a different perception towards conflict management due to the length of their life and work experience.

8.1.3 Years of Experience in the Construction industry

Figure 8.1.4 Number of years of experience which the respondents had within the construction industry.

As shown in figure 8.1.4, 33% of the respondents had more than 20-30 years of experience within the construction industry, 24% of the respondents had 10-20 years of experience, 14% of the respondents had more than 30 years of experience and 29% of the respondents had less than 10 years of experience. These respondents worked in a range of middle to senior management positions. Senior managers focus on strategic views whilst middle managers focus on efficient project operation and younger managers bring creativity into the workplace.

8.1.4 Size of Projects

Figure 8.1.5 Size of projects which the respondents' organisation usually undertook.

71% of the respondents worked in large corporations which usually undertook big project in access of more than \$30 million. Usually, the larger projects have more complexity and risks associated than smaller projects and so are more likely to encounter disputes.

8.1.5 Contractual disputes encountered during the past five years

Figure 8.1.6 Number of contractual disputes encountered by the respondents during the past five years.

As shown in the pie chart above the 72% of the respondents encountered between one to three disputes during the past five years.

8.1.6 Types of Dispute

Figure 8.1.7 most common type of disputes which were encountered by the respondents who participated in the research.

As shown in figure 8.1.7 the most common types of dispute encountered by the respondents were all related to money, in particular 37% of the disputes were related payment for variation, 17% of the disputes were related to quality of materials and 14% of the disputes were extensions of time.

8.1.7 Most commonly used Dispute Resolution Methods

Figure 8.1.9 Most commonly used dispute resolution methods by the respondents who participated in the research.

As shown in figure 8.1.9 negotiation was the most commonly used method for dispute resolution followed by mediation. Respondents preferred to negotiate at all times to resolve disputes.

8.1.8 Overall satisfaction with the current dispute resolution methods

Figure 8.1.10 Overall satisfaction of how the current dispute resolution methods are operating in relation to their response in 8.1.9.

Respondents were most satisfied when negotiation was used for dispute resolution. Through the interviews, respondents were most satisfied with the outcome of negotiation and emphasised the importance of excellent communication skills and the preservation of relationships in the Melbourne construction industry.

8.2 Analysis of Interview Responses -Perception of the current operation of dispute resolution methods in Melbourne

Participants were asked to comment on the efficiency of the dispute resolution processes in Melbourne. Every respondent agreed that litigation was the least efficient and

preferred method as it was time consuming, costly with no guarantee of satisfactory results and was just a 'revenue for the lawyers'. Of the twenty one respondents, thirteen professionals were moderately satisfied with the current operation of mediation in terms of the time involved in the process and outcome. Three respondents did not have any strong opinion towards any ADR methods as they felt dispute resolution 'was just part of their job in project management' as the Melbourne construction industry has an adversarial work culture. Five of the respondents felt confident about their negotiation ability to resolve conflicts and the ability to maintain relationships with their contractors and subcontractors as they only collaborated with people they knew.

Participants were then asked if they felt that an unresolved issue often had a detrimental impact on the cooperation, coordination and communication between parties before the conflict is transformed into a dispute. Sixty five percent of the respondents commented that with any conflict that arises cooperation between parties always broke down first. Thirty percent of the respondents felt that communication became the most difficult task as unsatisfied parties were often unresponsive to written confirmations and other correspondence requests. One project manager stated that when subcontractors and contractors became uncooperative the problem of coordination delayed the project. All respondents emphasised on the importance of preserving relationships in the Melbourne construction industry.

8.3 Perception and concerns of the Dispute Review Board method

Positive Perception of DRB	Concerns regarding DRB
Experts will be involved in the project very early with the formation of DRB clause into the contract at the commencement of the project.	Practicality of achieving qualities of neutrality, impartiality and independence in the selection, nomination and appointment of the DRB members
Selection process is open.	Melbourne Construction industry is relatively small and more reliant on relationships than US market.
Fairness can be achieved in the extent that both parties agree on the other party's choice of member.	Adequate knowledge of DRB members in all stages of the project.
Use lawyer is discouraged.	Fairness may not be achieved if influenced by political interests.
Independence could be achieved as board members have no financial ties with any party.	DRB's function is perceived to be very similar to a panel of three expert witness so impartiality may not be achieved.
DRB will enhance cooperation among the project manager, the owner and the contractor as all parties have the intention to abide by the board's ability to make decisions and investigate any unreasonable behaviour when the board is formed at the start of the project.	Use of Design and Construct contracts may not be suitable for DRB design is not fully documented before the construction starts therefore the experts' knowledge of the design documentation is limited.
Incorporate a spirit of cooperation among parties.	that the periodic site visits needed to be weekly and at the end of every milestone to effectively mitigate conflicts transforming into disputes.
	Adversarial attitude between will not improve if DRB members can determine the liability before the conflicts turn into a dispute as the notion of liability is subjective.
	Fee of 0.05%-0.25% of the total project costs was too high to be factored into the overall construction cost
	preservation of relationships is not a strong enough incentive for most respondents to implement the DRB at the current cost structure
	small matters can inflate unnecessarily with the existence of the DRB whereas before, the matter could have been resolved through private negotiation.
	Whether decisions be accepted depends on the person and their credibility.

8.4 Importance of the selection criteria for dispute resolution methods

Respondents were asked to rank on a 1-5 likert scale the perceived importance of the ten criteria in the selection of dispute resolution methods. Results from the Relative Importance Indices analysis are displayed in table 5.1.

Table 8.4: Importance of Factors which may influence the selection of dispute resolution methods

Criteria	Total Score	RII*	Rank
Cost	105	1	1
Open and fairness	98	0.933	2
Speed	98	0.933	2
Privacy and Confidentiality	65	0.619	8
Outcome	98	0.933	2
Enforceability	83	0.79	6
Relationship	88	0.838	5
Flexibility	63	0.6	9
Creative remedies	51	0.486	10
Control	70	0.667	7

*RII= Relative Importance Index

Results indicate that the cost, with the highest ranking of 1, was the most important criteria when considering the selection of dispute resolution methods. The second most important factor in the selection of the dispute resolution methods are open and fairness, speed and outcome. Preservation of relationship and enforceability was the third most important factor when considering methods of dispute resolution. Degree of control ranked 7 and privacy and confidentiality ranked 8. The ranking of this research demonstrates that respondents are primarily concerned with the tangible benefits of dispute resolution. However, preservation of relationships is crucial for the Melbourne construction industry. Flexibility scored a lower ranking of 9 and creative remedies scored the lowest ranking of 10. This indicates that respondents are less concerned with *how* disputes are resolved but focus on the results of the outcome.

9 Conclusion

Negotiation is still the preferred method of dispute resolution in Melbourne. Cost achieved the highest ranking RII value of 1 indicating that it was the most important performance criteria when in the selection of dispute resolution methods. Other critically important factors are speed, outcome, open and fairness as well as relationships. Flexibility and creative remedies received the lowest ranking score of 9 and 10 in RII indicating that in the context of project management professionals are more interested in the immediate tangible outcome when selecting dispute resolution methods than long term intangible benefits such as improvement in the process of dispute resolution for future benefits.

The spirit of cooperation is evident in the dispute review board but is inadequate to improve adversarial attitude between parties. Extensive training at the graduate level is needed in order to change the general attitude of the high level of resistance to change in Melbourne. The notion that “things can’t improve” and “disputes is just part of the job in this industry” hinders the potential for the Melbourne construction industry to develop in full capacity and compete at international level.

Further research can be done in the field of organisational change and learning to improve the training in organisational leadership and conflict management in project management.

Abstract:

Currently litigation and arbitration are too time consuming, costly and damaging in business relationships whilst Alternative Dispute Resolution (ADR) methods such as mediation and conciliation are increasing becoming formal and costly. This research examined the stakeholders' perception of the Dispute Review Board (DRB) in managing conflicts in construction projects and assessed whether the performance of DRB may achieve a better dispute resolution outcome than other dispute resolution methods. This research involved construction professionals with experience in dispute resolution. Survey questionnaire was used to find out the perception on the use of the DRB using the ten criteria, namely cost, speed, outcome, enforceability, privacy and confidentiality, open and fairness, control, flexibility, creative remedies and relationships. The results found that DRB is perceived to have a comparative advantage in nearly all criteria over litigation and arbitration and has a higher comparative advantage in the capacity to maintain relationships when compared with mediation and conciliation. Structured interviews were also used to examine the perception of the DRB and found concerns regarding the use of DRB are costs, distrust as well as the general attitude of resistance to change in the adversarial Melbourne construction industry. Recommendations for areas where DRB can be improved are discussed to suit the Melbourne construction industry. This paper demonstrates that the suitability of the Dispute Review Board in Melbourne requires more than good faith and willingness to implement the mechanism as the Dispute Review Board is still an external party representing formal authority and governance over the complex process of the construction management.

Keywords:

dispute review board, alternative dispute resolution, Melbourne construction industry, performance of dispute review board, comparative advantage

1 Introduction

Disputes are a significant factor that causes project delays. Less than 50% respondents are satisfied that the dispute resolution methods used were effective in terms of cost,

outcome, time and process (Dawson, 2007). Project level negotiation and executive negotiation resolution methods were resolved disputes in less than three month and 16% of disputes using other methods such as mediation took over 12 months to resolve (Dawson, 2007). Litigation and arbitration are notoriously cost inefficient and time consuming but above all, it breaks goodwill between business relationships, which is detrimental to the nature of the construction industry, heavily reliant on collaborative teamwork (Sprague, 2006). Another problem associated with litigation and arbitration is that it can also have adverse effects on the construction programme and the quality of the works, irrespective of the size of the project (Cheung, 1995) (Bailey, 1998). Combined with the increasing formality of Alternative Dispute Resolution (ADR) these systems will eventually increase in the costs involved hence in future, most disputes will need to be resolved on site (Miles, 1996). For these reasons, the Dispute Review Board (DRB) may improve the current dispute resolution system if it is implemented in Melbourne.

The Dispute Review Board (DRB or DB) is a Dispute Avoidance Procedure method to settle various construction dispute claims (Gerber, 2001). Other ADR techniques include voluntary negotiations between the parties; third party assisted negotiations such as mediation, conciliation and adjudication; and adversarial approaches such as arbitration or litigation (Sprague, 2006). The Melbourne construction industry is based more on relationships than most others and as a result dispute resolution using ADR methods, such as mediation allow flexibility in addressing technical issues and preservation of relationships as well as minimising adverse publicity (Sprague, 2006) (Megens, 2005). However, sufficient attention should be directed to the dispute resolution clauses at the time of contract preparation to avoid costly, time consuming as well as distracting and ineffective dispute resolution processes later on. (Gould, 2006).

This research aims to explore the construction industry's stakeholders' perception regarding the use of the Dispute Review Board in managing conflicts in Melbourne construction projects. Additionally, this research aims to examine the potential effects of these conflict management mechanisms when compared with the other dispute resolution methods currently in use.

2 Conflict and Dispute

Conceptually a *conflict* is a difference between two or more beliefs, ideas, or interests (Collin *et al.* 1996). Based on the above definition conflict in construction may include dissatisfaction, disagreements over contract administrator's decisions, anger, hostility, and negative attitudinal propensities by parties (Aibinu *et al* 2008).

2.1 Disputes- When conflicts are unresolved

Dispute arises in a situation when a claim or assertion made by one party is rejected by another party and this rejection is not accepted (Kumaraswamy, 1998). A claim is an assertion of a right to money, and property, or a remedy and can be made under the contract itself, for breach of the contract, or for breach of a duty in common law (Powell-Smith and Stephenson, 1989). Construction claims can be in the form of money and time claims by the main contractor against the project owner for extension of contract time and additional payment arising from a specified event in the contract (Aibinu *et al* 2008). The claim can be any application to the project management team

pursuant to any relevant clause of the contract including any variation to payments, extension of time and or damages for any alleged breach of duty by the employer or employer's management team (Kumaraswamy, 1998).

3 Dispute Resolution Methods

The common dispute resolution methods operating in Melbourne are litigation, arbitration, mediation, conciliation, adjudication, mini-trials, facilitated negotiation, partnering and expert determination.

3.1 Litigation

Litigation is a legal proceeding in a court or a judicial context to determine and enforce legal rights (Hill, 2008). This is the least preferred method in the construction industry as the courts act on the adversary system (Bailey, 1998) and damage business relationships (Sprague, 2006). Besides the slow, expensive, time consuming, risky and stressful procedure which litigation brings, there is no real certainty of results other than a certainty of at least one loser (Merritt, 2006).

3.2 Arbitration

Arbitration is a mini-trial for a law suit ready to go to trial, held in an attempt to avoid a trial and is conducted by an independent person, usually with some relevant skill or knowledge, to determine the dispute (Bailey, 1998). During the arbitration process, parties make submission to an arbitrator and are bound by the arbitrator's decision (ACDC, 2005).

3.3 Mediation

Mediation is a prominent ADR method used in the Melbourne construction industry and is now a firmly established preferred dispute resolution tool for construction claims (Megens, 2005). Mediation is an attempt to settle a legal dispute through an active participation of a third party, a mediator, who works to find points of agreements and make those in conflict agree on a fair result (Hill, 2008). Resolution is attempted but settlement is not always achieved (Hill, 2008).

3.4 Conciliation

Conciliation is similar to mediation however the main goal is to conciliate by seeking concessions.

3.5 Adjudication/Security of Payment

Adjudication is the process where an independent person, the adjudicator, makes a determination as to the amount, if any, which the respondent owes to the claimant, on a specific date it was (or will be due) to be paid and on what interest applicable (IAMA, 2006). The objective is to impose a settlement on parties.

3.6 Mini-Trials

Mini-trials are a structured information exchange attended by representatives authorised to settle the dispute and are used where a dispute exists between the key decision makers of both parties (Sprague, 2006).

3.7 Facilitated Negotiation

Facilitated negotiation involves an independent and objective person which enters the negotiation session to assist the parties in reaching agreement (Berman, 1995). The purpose is to facilitate a mutual understanding of both parties rather than settlement (Sprague, 2006).

3.8 Expert Determination/Appraisal

Expert determination is a person who a specialist in a technical subject who may present his or her expert opinion without having been a witness to any occurrence relating to the lawsuit or criminal case (Hill, 2008). The critical areas of importance for the 'expert' are to remain independent of, and act fairly and impartially between parties and to adopt a suitable procedure whilst avoiding unnecessary delay and expense in the given circumstances (Sprague, 2006).

3.9 Partnering in Alliance Contracting- towards proactive dispute avoidance

Partnering is a project procurement method where the parties to the contract share a common goal aim to complete the project successfully (Sprague, 2006). This is achieved by sharing both the benefits and risks of the project. Partnering is a proactive dispute avoidance technique. It is based on relationships and trust that all parties share a common goal (Eilenberg, 1996). Under this procurement method, a contract is set up with an agreed target price and incentives for parties.

4 Dispute Review Board-Overview of the structure, components and use

The Dispute Review Board (DRB) consists of three *qualified* members committee, nominated by *both parties*, formed at the *start of the project* and meet periodically *on site* to discuss issues (DRBF, 2007). Then they form non- binding recommendations. If the parties are *unsatisfied*, they can turn to other methods of binding or non-binding methods of such as mediation and conciliation or any other ADR methods (DRFB, 2007).

4.1 Selecting, nominating and appointing Board Members

The three members nominated by both parties (Gould, 2006) :

They must not have any financial ties to any party either directly or indirectly involved in the contract, not be currently employed by any party directly or indirectly in respect of the contract, and

Not have a close professional or personal relationship with a key member of any party directly or indirectly involved in the contract that could give rise to the perception of bias

Each party selects one member which is approved by the other party and then a third member is chosen by the two selected members. The three DRB members then selects one as the chair with the approval of both the contractor and the owner.

Members must be qualified in both the technical and legal facets of construction practices and methods.

4.2 Formation of DRB clause into the contract at the commencement of the project (Gaitskell, 2005)

When DRB is established before the commencement of the project, the members will have the relevant design documentations, specifications and project scope as well as understanding the contract conditions.

4.3 Periodic visits on site to resolve issues (Gaitskell, 2005)

Meeting 3 to 4 times a year or more frequently as agreed by both parties

Issues are seen, heard and resolved as they arise on site.

4.4 Issuing non-binding recommendations (Gaitskell, 2005)

DRB can act as a flexible and informal advisory panel. Before issuing a recommendation, the DRB may be asked for general advice on any particular matter. The DRB would then look at documents and or visit the site as appropriate and most usually, provide an informal oral recommendation, which the parties may choose to adopt.

If the parties were not satisfied, the DRB would follow the formal procedure of exchange of documents and a hearing and afterwards issue a formal written recommendation.

The decisions made by the board are non-binding but are generally accepted by the parties due to the merit of the expert opinion been admissible of the matter proceeds to arbitration or litigation.

4.5 Costs associated to implement the Dispute Review Board (DRBF, 2007)

The fees will be shared by both parties.

The fees will range between 0.05%- 0.25% of the project value and will act as an insurance premium against potential hefty dispute costs if the claim progresses to litigation and arbitration.

5 Factors which impact upon the performance and selection of Dispute Resolution Methods

There are ten factors used to test the performance and selection of dispute resolution methods namely, cost, speed, outcome, enforceability, privacy and confidentiality, open and fairness, control, flexibility, creative remedies and relationships as identified by Cheung *et al*, (2002).

5.1 Cost

The direct fees for the DRB ranging from 0.05% to 0.25% of the total construction cost. The fees are shared by both parties which mitigate the conflict of interest and perception of bias that *all three* DRB members will take one particular side. In mediation,

conciliation and other current ADR methods operating in Melbourne, there is only *one* member facilitating the negotiation for settlement between two parties.

5.2 Openness, Neutrality and Fairness

Neutrality, openness and fairness are the core values of the DRB. The board members must not have financial ties with any party. If there is a conflict of interest, it must be disclosed to all parties. The selection process for the DRB members is a consensus approach.

5.3 Speed

The DRB is established before the commencement of the project. It will involve the experts every early on the project and potential claims dispute may be identified *before* the issues surfaces as the conflict is resolved as they arise *on site* where as the current ADR methods in Melbourne resolve disputes *after* the event has occurred. This solves the problem of delaying the time to sort out missing documentation and historical information to make an accurate determination. Additionally, the periodic site visit will improve the adversarial nature between conflicting parties when liability can be determined before the conflict turns into a dispute.

5.4 Outcome

The DRB has the flexibility of acting as an advisor as well as issue non-binding recommendations. The use of lawyers on the board is discouraged to avoid an adversarial climate however the question of liability is ruled upon by *three* members. This should encourage the parties to accept the board decisions especially if the contract language includes a provision for the admissibility of a DRB recommendation into any subsequent arbitration or legal proceeding.

5.5 Privacy and Confidentiality

The code of ethics for DRB stipulates that the DRB must keep all information arising from the DRB review and hearing confidential and since the dispute is resolved on site, no external party will know that an issue exists. This should preserve business relationships and prevent any unnecessary complexity which may arise from external parties after hearing about the dispute.

5.6 Enforceability

The DRB is non-binding however, the goal of the DRB is facilitate the conflicting parties to resolve their differences so that construction works can continue on site.

5.7 Preservation of Relationships

Both parties agree on the selection of the DRB members at the appointment of the board. This means that all parties are willing to cooperate with each other in good faith and trust the board's decision making abilities when a conflict arises. If the parties are unsatisfied with the decisions of the DRB, they are free to sort dispute resolution methods.

5.8 Flexibility

The DRB can act as a flexible panel acting as an advisor which will facilitate the negotiation process more than the current ADR methods which can only act as a neutral

facilitator as with mediation or act to make a judgement of a technical issue as with expert determination. Litigation and arbitration are the least flexible methods as it is only interested in the issue which relate to a point of law and does not take into account of any other factors.

5.9 Creative Remedies

The DRB is a panel of three experts with different but relevant qualifications, skills and more than ten years of experience within the construction industry. The blend of qualifications and experience of the three-person DRB can provide a powerful combination of decision-making abilities than one person trying to make a judge within their limits of understanding and experience which is the case with expert determination.

5.10 Degree of Control

As mentioned before, the DRB members are agreed upon by both parties and the board resolves issues on site. The board can also act as an advisory panel which is not possible with the current operation of ADR methods. These factors give both parties a feeling of being control of the outcome and processes involved to reach an agreement.

6 Methodology

The entire process comprised of a a structured interview and a questionnaire.

Questionnaire: There were 10 survey questions asking the respondents to rank from the likert scale of 1 to 5 (1 for extremely disagree, 5 for extremely agree) using the ten criteria factors, the respondents were asked to rank each of the criterion on whether they agree or disagree that the performance of DRB has a comparative advantage over the eight other dispute resolution methods.

Interview Questions: The respondents were asked to read some information regarding the use of DRB and they were asked questions regarding their perception of the DRB as well as any concerns regarding the implementation of the mechnism in the Melbourne construction industry.

6.1 Population and Sample

The population sample was restricted to the Melbourne industry. The research sample consisted of twenty one respondents which undertook both the structured interview and questionnaires. The research sample included: five architects, three engineers, three quantity surveyors, two development managers, three project managers, one project director, one CEO, one site foreman and two construction managers. Fifteen of these participants had over ten years of experience in their respective field of work. Eighty percent of the respondents answered that the project size their company generally undertake is in excess of \$10 million. The average number of disputes that each building professional had been involved in over the last five years was five which confirms that these respondents have had a reasonable level of experience.

6.2 Data Analysis Tool

6.2.1 Structured Interview Analysis

The structured interview has been analysed using the ‘grounded theory’ approach, an example can be referred in Strauss and Corbin (1998).

6.2.2 Questionnaire Survey data analysis

To measure the performance of the conflict management mechanisms of the DRB in comparison with other dispute resolution methods two mathematical equations were used for the analysis of the quantitative data. There are Relative Performance Index (RPI) and Relative Attractiveness (RA) for each dispute resolution method.

Step 1. Relative Performance Index

To determine the performance of any dispute resolution method when compared with DRB on each criterion, the respondents’ ratings are transformed in Relative Performance Index (RPI) for each criterion. RPI is computed using the following mathematical expression:

$$RPI = \sum W_i / (A \times n) \dots \dots \dots \text{equation 1}$$

Where $\sum W_i$ is the total score assigned importance of a decision criterion by all the respondents;

A is the highest weight (5; and

n is the number of respondents

The computed RPI are then ranked for each dispute resolution method on each criterion. The areas of comparative advantages of the DRB over dispute resolution method on each criterion were identified.

Step 2. Relative Attractiveness

The next step is to evaluate the relative attractiveness (RA) of each dispute resolution method on each of the 10 criteria. This may be obtained by combining the Relative Importance Index (RII) of a criterion and the Relative Performance Index of that criterion. This may be obtained using the following model:

$$RA_a = (RII_a) (RPI_a) / 25 (\%) \dots \dots \dots \text{equation 2}$$

Where:

RA_a = Relative Attractiveness of a dispute resolution method on criterion ‘a’

RII_a is the Relative Importance Index of criterion ‘a’

RPI_a is the Relative Performance Index (RPI) of a dispute resolution method on criterion ‘a’

7 Results

7.1 Interview responses-Perception and concerns of the Dispute Review Board method

After reading the information regarding the structure, components and use of the DRB, sixty two percent of the respondents had concerns regarding the practicality of achieving the qualities of neutrality, impartiality and independence in the selection, nomination and appointment of the DRB members. These respondents felt that the Melbourne construction industry is relatively small therefore it is even more reliant on relationships than compared with the US market. One respondent had concerns regarding the adequate knowledge of the DRB members. The construction process is made up of different stages requiring different specialists in each stage. The three members may not be knowledgeable for all facets and stages of project management.

Another respondent stated that the selection process was open but did not necessary achieve fairness as humans are always influenced by political interests. Ten percent of the respondents perceive the DRB's function being very similar to a panel three expert witnesses providing technical knowledge therefore they do not have full faith in the impartiality of the board members although the board is paid by both parties. The negative attitudes highlight the lack of trust among the parties within the highly adversarial Melbourne construction industry. However, twenty percent of the respondents felt that independence could be achieved as the board members have no financial ties with any party. Furthermore, the both parties agree on the other party's chose of member so fairness is achieved in this extent.

Eighty five percent of the respondents agreed that the formation of the DRB clause into the contract at the commencement for the project will involve the experts very early on the project as they will have the relevant design documentations, specifications and project scope as well as understand the contract conditions. It will also incorporate a spirit of cooperation among the parties. However, twenty percent of the respondents also noted that for potential claims dispute to be identified before the issue surfaces is dependent on the particular job, type of contract used, the parties involved as well as the effective management of the board. The use of Design and Construct contracts may not be suitable for the DRB as the selection of the board members may be time consuming and delay the commencement of the works. Furthermore, in a Design and Construct contract, design is not fully documented before the construction starts therefore the experts' knowledge of the design documentation is limited.

Fifty percent of the respondents felt that the periodic site visits needed to be weekly and at the end of every milestone to effectively mitigate conflicts transforming into disputes.

No respondent felt that the adversarial nature between conflicting parties will improve with the DRB members settling conflicts quickly whilst the job is in progress when the liability can be determined as the notion of liability is subjective. Thirty percent of the respondents expected the project manager to be able to identify any risks which may develop into a dispute.

Ninety five percent of the respondents felt that the DRB member's fee of 0.05%-0.25% of the total project costs was too high to be factored into the overall construction cost planning budget. However, one respondent believed that a lump sum would be viable.

Eighty percent of the respondents feel that the DRB will enhance cooperation among the project manager, the owner and the contractor as all parties have the intention to abide by the board's ability to make decisions and investigate any unreasonable behaviour when the board is formed at the start of the project. However, the preservation of relationships is not a strong enough incentive for most respondents to implement the DRB at the current cost structure. Thirty percent of the respondents argued that certain small matters can inflate unnecessary with the existence of the DRB whereas before, the matter could have been resolved through private negotiation. All the respondents felt positive that the use lawyer is discouraged.

7.2 Performance of Dispute Resolution Methods on the 10 criteria

Results from the analysis of the Relative Performance Indices (RPI) are displayed in table 7.1

Table 7.1 Performance of any dispute resolution method in relation DRB on each criterion

Dispute Resolution Methods	Cost		Open and Fairness		Speed		Privacy and Confidentiality		Outcome		Enforceability		Relationships		Flexibility		Creative remedies		Control	
	RPI*	Rank*	RPI	Rank	RPI	Rank	RPI	Rank	RPI	Rank	RPI	Rank	RPI	Rank	RPI	Rank	RPI	Rank	RPI	Rank
Mediation	0.562	5	0.676	5	0.676	5	0.686	5	0.676	3	0.552	3	0.752	3	0.705	3	0.705	3	0.676	5
Conciliation	0.562	5	0.676	5	0.676	5	0.686	5	0.676	3	0.552	3	0.752	3	0.705	3	0.705	3	0.676	4
Mini-Trial	0.591	3	0.714	3	0.714	4	0.705	3	0.657	6	0.561	2	0.733	5	0.705	3	0.686	6	0.657	6
Expert Determination	0.581	4	0.705	4	0.724	3	0.7143	4	0.676	3	0.6	1	0.672	7	0.705	3	0.705	3	0.705	3
Litigation	0.752	1	0.752	1	0.752	1	0.8	1	0.695	1	0.467	7	0.762	1	0.724	1	0.724	1	0.724	1
Arbitration	0.752	1	0.752	1	0.752	1	0.8	1	0.695	1	0.467	7	0.762	1	0.724	1	0.724	1	0.724	1
Partnering (Procurement Method)	0.552	7	0.638	8	0.552	7	0.629	7	0.6	7	0.513	6	0.695	6	0.657	7	0.6	8	0.543	7
Negotiation	0.391	8	0.676	7	0.448	8	0.6	8	0.572	8	0.543	5	0.6	8	0.439	8	0.657	7	0.533	8

*RPI= Relative Performance Index factors. *Rank=The higher the ranking, the higher the DRB has comparative advantage over other dispute resolution methods on the criterion.

Results from the RPI demonstrate that for the criterion of cost, the DRB was perceived to have comparative advantage over litigation and arbitration, followed by mini-trial and expert determination. However, when compared with negotiation, the DRB was perceived to have no comparative advantage.

For the criterion of open and fairness, the DRB was perceived to have a comparative advantage over litigation and arbitration, followed by mini-trial and expert determination. But when compared with partnering, the DRB was perceived to have no comparative advantage.

For criterion of speed, the DRB was perceived to have a comparative advantage over litigation and arbitration, followed by mini-trial and expert determination. Again when compared with negotiation, the DRB was perceived to have no comparative advantage.

For the criterion of outcome, the DRB was perceived to have a comparative advantage over expert determination, litigation and arbitration but have no comparative advantage over negotiation and partnering.

For the criterion of enforceability, DRB has no comparative advantage over litigation and arbitration but when compared with expert determination, followed by mini-trial and mediation and conciliation the DRB has a comparative advantage. The non-binding nature of DRB was perceived to be similar to the non-binding nature of mediation and conciliation but preservation of relationships was perceived to have a higher comparative advantage in DRB than mediation and conciliation.

For the criterion of privacy and confidentiality the DRB was perceived to have a comparative advantage over litigation and arbitration but no comparative advantage over mediation, conciliation, negotiation and partnering.

For the criterion of creative remedies the DRB was perceived to have a comparative advantage over litigation, arbitration, conciliation and mediation but no comparative advantage over partnering, negotiation followed by mini-trial. Mini-trial allows parties to get an insight into the potential outcome which might be generated if the case progressed into a real litigious trial which may explain why the DRB was perceived to have no comparative advantage.

For the criterion of degree of control, the DRB was perceived to have a comparative advantage over litigation, arbitration, mini-trial, expert determination, as well as mediation and conciliation but have no comparative advantage over negotiation and partnering. This is due to the perception that board members are agreed by both parties upon the appointment of the board. However negotiation and partnership is a private process where there are no set rules, process and outcome of dispute resolution therefore 80% of respondents still feel more in control in the 'muddy pool' of negotiation.

For the criterion of relationships, the DRB was perceived to have a comparative advantage when compared with litigation, arbitration, mediation and conciliation. This demonstrates that resolving issues on site is perceived to enhance the cooperation between parties to settle issues quicker than resorting to an external third party.

For the criterion of flexibility, the DRB was perceived to have a comparative advantage over litigation, arbitration, followed by expert determination, mediation, conciliation

and mini-trial but no comparative advantage over negotiation and partnering. This result confirms that the DRB can act as a flexible panel acting as an advisor which will facilitate the negotiation process more than the current ADR methods which can only act as a neutral facilitator as with mediation or act to make a judgement of a technical issue as with expert determination. Litigation and arbitration are the least flexible methods as it is only interested in the issue which relate to a point of law and does not take into account of any other factors.

For the ten criteria, there is a pattern that the DRB has no comparative advantage over negotiation and partnering but has a comparative advantage over litigation, arbitration and mini trial. The pattern demonstrates that the respondents still perceive the conflict management mechanisms of negotiation and partnering potentially performing a better dispute resolution using all ten criteria excluding enforceability.

7.3 Attractiveness of DRB when compared with other dispute resolution methods.

Results from the analysis of the Relative Attractiveness (RA) of each ADR methods are displayed in table 7.2

Table 7.2 Evaluation of the Relative Attractiveness (RA) of the dispute resolution methods on each criterion

Dispute Resolution Methods	Cost		Open and Fairness		Speed		Privacy and Confidentiality		Outcome		Enforceability		Relationships		Flexibility		Creative remedies		Control	
	RA *	Rank	RA	Rank	RA	Rank	RA	Rank	RA	Rank	RA	Rank	RA	Rank	RA	Rank	RA	Rank	RA	Rank
Mediation	2.248	5	2.523	5	2.523	5	1.699	5	2.523	3	1.744	3	2.521	3	1.692	3	1.371	3	1.804	4
Conciliation	2.248	5	2.523	5	2.523	5	1.699	5	2.523	3	1.744	3	2.521	3	1.692	3	1.371	3	1.804	4
Mini-Trial	2.364	3	2.665	3	2.665	4	1.746	4	2.452	6	1.773	2	2.457	5	1.692	3	1.277	6	1.753	6
Expert Determination	2.324	4	2.631	4	2.702	3	1.768	3	2.523	3	1.896	1	2.253	7	1.692	3	1.371	3	1.881	3
Litigation	3.008	1	2.806	1	2.807	1	1.981	1	2.594	1	1.476	7	2.554	1	1.738	1	1.408	1	1.932	1
Arbitration	3.008	1	2.806	1	2.807	1	1.981	1	2.594	1	1.476	7	2.554	1	1.738	1	1.408	1	1.932	1
Partnering (Procurement Method)	2.208	7	2.381	8	2.06	6	1.558	7	2.239	7	1.621	6	2.33	6	1.577	7	1.056	7	1.449	7
Negotiation	1.564	8	2.522	7	1.672	7	1.486	8	2.135	8	1.716	5	2.011	8	1.054	8	1.036	8	1.422	8

*RA= Relative Attractiveness of factors

Results from RA indicates that for the criteria of cost, open and fairness, speed, privacy and confidentiality and outcome, respondents perceived the DRB as relatively more

attractive when compared with litigation, arbitration, followed by mini-trial and expert determination. But for the criteria of negotiation and partnering, the DRB has no comparative advantage in terms of attractiveness of preference.

For the criterion of enforceability the DRB was perceived as relatively more attractive when compared with expert determination, mini-trial, mediation and conciliation but have no comparative advantage over litigation, arbitration, partnering and negotiation.

For the criteria of creative remedies and degree of control the DRB was perceived as relatively more attractive when compared with litigation, arbitration, expert determination, mediation and conciliation but have no comparative advantage over mini-trial, negotiation and partnering.

Results combining the RPI and RII together demonstrated a perception of the respondents' preference in the selection of dispute resolution methods.

8 Conclusion

The results from the analysis of interview responses and questionnaire survey demonstrates that when compared with litigation and arbitration the DRB is perceived to have a comparative advantage in 9 out of 10 criteria which are namely cost, open and fairness, speed, privacy and confidentiality, outcome, relationships, flexibility, creative and control. The DRB is perceived to have a comparative advantage in the capacity to maintain relationships when compared with mediation and conciliation. This indicates that the building professionals feel that *on site* resolution of issues improves communication and cooperation between parties. When compared with negotiation and partnering the DRB was perceived to perform have no comparative advantage indicating that informal negotiation is still the preferred method of dispute resolution in Melbourne. The concerns which building professionals in Melbourne have regarding the use of DRB arise from the high costs of employing DRB members, a lack of faith in the board's ability to achieve qualities of neutrality and impartiality in the selection of board members resulting from the perception that Melbourne construction industry is so reliant on networks and relationship, and as well as the general attitude of resistance to change in the adversarial construction industry.

If DRB is to be implemented successful in the Melbourne construction industry, site managers and site foreman will need to be directly involved in the process of decision making for dispute resolution to effectively resolve issues on site. The advantage is that they understand the subcontractors as a large proportion have a trade background in their training. This will improve the adversarial climate between conflict parties as lot of subcontractors do not like to deal with office personnel but will communicate with the site managers because they feel that site managers are the only ones who understand how a building is physically built.

The DRB will not be very effective if the project manager with the power of decision making and reporting obligations only found out about an arising conflict at the same time the DRB was informed to investigate an issue. This may involve an adjustment in the organisational structure of decision making and consequently, pose challenges for the project managers to accept a partial proportion of their decision making power to be shared by site managers.

Industry bodies such as Masters Builder Association Victoria (MBAV) and the Housing Institute of Australia (HIA) need to get involved to convince the government to initiate a DRB project. The DRB may have some impact to how the union currently operates in construction. Any potential conflict of interest in power will require legislation to resolve any potential clash.

Abstract:

Litigation as a formal way of dispute resolution is time consuming, costly, adversarial and damages, if not destroys, relationships and reputations. There are many alternative forms to litigation and arbitration, also in Kuwait different organisations prepared regulations for different forms of alternative dispute resolution. These forms have been rarely used due to cultural difficulties and to lack of awareness of these forms of dispute resolution.

In addition to exploring the advantages of using the alternative dispute resolution forms with construction projects disputes, this paper presents the findings of what alternative dispute resolution strategies are currently been implemented by different organisations in Kuwait. These finding are reinforced by interviews conducted in Kuwait, with workers in the construction industry, to identify the main reasons, in terms of culture and awareness aspects, for not adopting ADR in construction disputes. The barriers to use mediation are found to be, mainly, lack of awareness and another six cultural aspects. However, elimination instruments to the barriers were revealed in this study.

Keywords:

alternative dispute resolution ADR, awareness, Kuwait construction industry KCI, culture, mediation

1 Introduction

Although two forms of alternative dispute resolution ADR (mediation and conciliation) exist in two different documents produced by two bodies in Kuwait, these ADR guidance are rarely been used because of some barriers. A two-stage interview survey was conducted in Kuwait to investigate the need for ADR in the construction industry and the preferred form of ADR by industry and the reasons of preferring the named form. Furthermore, the causes of the delay of employing the existing forms of ADR in construction industry were under focus.

The cultural and knowledge barriers to employing different ADR forms in Kuwait were explored during the conducted interviews. Different themes from the open ended

questions were found. In addition, several suggestions to eliminate these barriers were recommended from the interviewees.

As a part of an ongoing PhD which explores the possibility of implementing different forms of ADR to settle construction disputes in Kuwait, this study highlights the barriers to employing the existing forms of ADR in settling construction disputes. In particular, barriers to the use of mediation were researched through two sets of interviews conducted in Kuwait with 27 specialists in the construction industry of Kuwait from different sectors. The interviewees' perspectives provide a representation view and were picked randomly. All 27 interviewees, in both stages, were chosen randomly from different sectors based on their experience in the construction industry as well as their familiarity with construction disputes in the private sector.

Briefly, findings of this study can be summarised under two main headings: lack of awareness in mediation; and cultural concerns to use mediation. These matters were found to be the main barriers to the employment of mediation in order to resolve construction disputes in Kuwait. Afterwards, the resolutions to these barriers to mediation were indicated in this brief study.

1.1 Aim and objectives of this study

This paper arises out of a PhD study seeking to improve dispute resolution in the Kuwaiti construction industry. The main aim of the paper is to explore the barriers to ADR in the Kuwaiti construction industry, which has been achieved through the following objectives are as follows.

To explore the requirements of Kuwaiti construction industry (KCI) in terms of resolving construction disputes in Kuwait.

To identify the barriers to ADR in KCI.

To recognise ways to overcome the identified barriers.

To identify and explore good practice and the role of ADR (mediation).

The mentioned objectives, of this paper, are the vital objectives of the whole PhD research, which are concentrating on the data collection and analysis chapters of the mentioned PhD.

1.2 Research limitations/difficulties

Respondents to such studies are difficult to be found, particularly in Kuwait, where the culture makes them keep their conflicts and disputes to the highest level of confidentiality. In which, small number of respondents who have got the desire to be interviewed replied to both interview stages' calls. Some respondents, because of confidentiality, have not answered every question that was asked in the interview. Some other interviewees declined to mention their project's titles, furthermore, some wished to remain anonymous. All respondents and the company names have thus remained confidential in this study, due to the commercial sensitivity of the subject.

Because of the low level of knowledge and lack of awareness in ADR, a preliminary session for the actual interviewees was used to ensure that they understood the concept

and principles of ADR and the aim of the whole session was to ensure non-bias and reliable data to eliminate the possibilities of unreliable outcomes. To ensure true judgement of the outcomes after the explanation session which was based on literature and been given before each interview, both interviews' questions and the above mentioned session was prepared by the authors and translated, from English to Arabic, with the assistant of independent expert. Additionally, during the transcription and analysis periods, translation (from Arabic to English) was a must. Translation in the transcription period was conducted directly by the authors and was checked by an independent body.

2 ADR forms in Kuwait

A review of the literature in Kuwait, in depth, proved that there are amicable alternative dispute resolution ADR regulations already in existence. These were prepared by: Kuwait Chamber of Commerce and Industry (KCCI) issued a document called (Nedham Al-Tawfeeq w Al-Tahkeem Al-Tejari: Conciliation and Commercial Arbitration System); and Kuwait Lawyers Association (KBAR) issued (Al-La'eha Al-Ejra'eyah w Al-Nedham Al-Asasi: The Procedural List and The Basic System). In addition, Kuwait Society of Engineers (KSE) which established a department called 'Kuwait Mediation and International Arbitration Chamber - under construction' they are preparing to issue a document called (Qawaed Al-Wasatta w Al-Tahkim Al-Ekhteyari fi Al-Masharie Al-Handasia: Regulations of Mediation and Optional Arbitration in Engineering Projects).

2.1 Conciliation

The Arabic translation of conciliation is "Al-Tawfeeq". Conciliation, as a commercial alternative dispute resolution in Kuwait has been provided by Kuwait Commercial Arbitration Centre which was established on the 14th of November 2000 as an accredited centre in KCCI. Although this document does not give the conciliator(s) in Kuwait the right to produce binding decisions, conciliator(s) can contribute towards convergence of views. To have the ability to consult The Kuwait Commercial Arbitration Centre, to use conciliation as a type of alternative dispute resolution, there needs to be the following clause included in the contract.

Any dispute arises upon this contract to be referred to the conciliation in accordance to the provisions contained in the Conciliation and commercial arbitration system of Kuwait commercial arbitration centre.

In addition to having this clause in the contract, to resort to conciliation, the disputants should have the desire to settle their dispute amicably and agree about conciliation. Agreeing to participate in the ADR processes is the most important movement towards choosing conciliation. This was found to be the main reason to why the usage of this and other types of ADR was poor. This conclusion was based on the interviews which will be discussed soon. The procedure of 'conciliation' in Kuwait is found to apply the conciliation regulations of the United Nations Commission on International Trade Law (UNCITRAL). The board of the centre forms an executive committee out of five members, which nominates the conciliation body in accordance with clause 14 of the previously mentioned document. The conciliation body contains either one member or more, who can be selected from the committee itself or externally, to conciliate in the dispute.

Clause 18 of the document states that the party who has the desire in conciliation submits a request to the secretariat of the centre. The request must include a list of the dispute's facts together with the applicant's point of view reinforced by supporting documents. From their side, the centre's secretariat informs the other party about the conciliation request within seven days from the submission day, the other party should reply within fifteen days from the date they were informed, expressing their point of view about the dispute.

The conciliation body studies the case and then invites the disputants for a hearing; the body's main mission is convergence of views, if they agreed about the final version of settlement, then this agreement should be signed. The conciliation body must finalise its mission within three months after their first meeting, extendable to another three months (if needed) by the committee's decision. In the case of a conciliation failure, the disputant's rights would not be affected with any shown or written during the conciliation processes. Finally, the centre provides the disputants, based on their request, with a certificate which describes how the centre viewed this dispute, the reasons why the conciliation trial was failed to settle it, without expressing any comments or views about the dispute.

2.2 Mediation

A role of mediation has been provided, on January 2004, by Kuwait Lawyer's Association Arbitration Centre which is a centre at the KBAR. In the introduction of their document, the general manager of the Centre, approved that "employing ADR is not ware or brand that we should mention its advantages anymore but it is a must which been imposed by the reality of today's international commercial".

Opposite to conciliation, the mediator is not contributing to the decision, nor are they pushing any of the disputants towards a settlement. Based on the previously mentioned documents, the main role of the mediator is to neutrally propose the effective procedure(s) towards an effective settlement for the dispute, as if they could do with resorting to expert determination in some points or to resort to arbitration in others. Resorting to *Al-Wasatta*, which is the Arabic translation of mediation, should be agreed by disputant parties of any contract. Again the following clause has been proposed by the general manager of the Kuwait Lawyer's Association Arbitration Centre.

In case of a conflict between parties upon explanation, application or implementation of this contract to be referred to the mediation process of the Lawyer's Association Arbitration Centre in the State of Kuwait in accordance to the procedural list and the basic system of the centre.

Another future role of mediation is under preparation and will be provided by The Kuwait Mediation and International Arbitration Chamber which was established on September 2010 by KSE. The main purpose of this chamber is to initiate roles of mediation and arbitration in construction disputes of Kuwait. Similar to conciliation, resorting to mediation should be agreed between parties in all cases, which can face different types of barriers although the role of mediation exists and useful. The barriers to mediation will be discussed in details derived from interviews held in Kuwait with workers in the construction industry who had experience in solved and unsolved disputes.

2.2.1 Regulations of mediation at Kuwait society of engineers

By late 2010, the KSE had established a department called The Kuwait Mediation and International Arbitration Chamber which is still under construction, this department is aiming to issue a document called (Qawaed Al-Wasatta w Al-Tahkim Al-Ekhteyari fi Al-Masharie Al-Handasia: Regulations of Mediation and Optional Arbitration in Engineering Projects) which should be concerning the dispute resolution in construction projects in specific and all types of engineering projects in general.

The Kuwait Mediation and International Arbitration Chamber's chief revealed that the main purpose of establishing this chamber under the society of engineers in Kuwait is to decrease resorting to litigation in order to resolve construction disputes. As they have found that litigation is an impediment to a project's progress and growth, they are intending to adapt the spirit of UNCITRAL regulations to be consistent with the *Kuwaiti Civil Code*. By then they will be ready to mediate in construction disputes. He added that the chamber will train mediators in the future to fill the needs of the construction industry in Kuwait.

2.2.2 Doubts to mediators

Brooker (2007) suggests that when a mediator 'gives advice or offers opinions' for any party in the dispute, this will affect the credibility of the mediator in which risks 'alienating' the whole process. Apparently, this is the case in the Kuwaiti culture, since it is a small community, which makes finding mediators without any type of relationships with one or both parties rare, if not impossible. In this regards, interviewees in Kuwait have been asked about the mechanism of trusting a third party while resolving construction disputes in Kuwait in terms of culture.

2.3 Section 2 in brief

The above recent findings gave the PhD research a new direction, since these regulations are not well-known and not been used regularly in resolving construction disputes. The essential issue of this study is that for some reasons the above detailed forms of ADR are not widespread, however, causes of this shortage were asked in the second stage of the interviews. It is always easier to resort to either mediation or conciliation if it is printed in the contract on the bases of previous agreement between parties, however, resorting to any amicable method of ADR (e.g. mediation and/or conciliation) is always voluntary for all disputants and it is all about the conformity between parties.

In fact, it is all about agreement between parties either before the occurrence of dispute, during the contracting phase, or yet after the dispute occurred between parties. In both cases, before or after the occurrence of dispute, the construction parties are always faced with existing barriers towards ADR. Although some interviewees preferred arbitration, just because it has a binding decision, most interviewees preferred mediation as an alternative dispute resolution in construction disputes. This suits the traditional Kuwaiti culture. For this reason, in this research, barriers to mediation in construction disputes will be considered only.

3 Methodology

A set of 11 qualitative interviews, furthermore, another set of 16 qualitative interviews were conducted in Kuwait with workers in the construction industry during October to December 2009 (1st set) and November to December 2010 (2nd set). Interviewees were selected based on their experience in construction disputes based on preliminary interviews conducted in Kuwait during December 2008 to February 2009 (Sayed-Gharib et. al., 2010). Face-to-face interviews are the most suitable method to collect data in Kuwait, for the sole reason that culture and the social environment in Kuwait depend on eye contact and direct conversation. That is why another stage with more detailed questions has been conducted latter on.

The first set of interviewees was selected randomly on the basis of their professionalism in construction projects and familiarity with construction disputes, regardless the sector that they were working for. Consequently, interviewees in this stage were selected from different sectors. For this reason, this stage of interviews was broad and open not as specific as the next stage of interviews, however, in the second set of interviews, all interviewees were selected for experience in construction disputes in the Private Sector. Finding interviewees, who have had experience in construction disputes, was with the help of the KSE and the KBAR in which these two organisations have got data of different types of workers in the construction industry who have been involved in disputes previously. The interviewees, in this stage, ought to be categorised as follows: three were reported as investors in construction projects; four consultants in construction field; and a further four experienced contractors in construction projects. Others were: three lawyers experienced in construction disputes; and two experts who act as third parties (i.e. mediators, conciliators and adjudicators) in construction disputes.

The data of the interview revealed that most workers in the construction industry believe that mediation gives a better deal, compromises a solution, shows neutrality, has a non-binding agreement unless signed, is a non-adversarial method, takes a shorter time, is a confidential process, is a flexible procedure, maintains relationships and it is a voluntary process.

Although most of the interviewees agreed that mediation offers massive amounts of benefits, participants commented on the barriers to workability of mediation in construction disputes in Kuwait. The data analysis established an approach to improve employing mediation against the mentioned barriers which frustrated the implementation of mediation in spite its existence in different industries institutes of Kuwait.

3.1 Data analysis

Both sets of interview data were analysed manually by taking matching themes from interviewees' responses. Considering that different words have different synonyms, and sometimes different synonyms have got different meanings. Nonetheless, translating the data from Arabic to English, added a difficulty of different translations. (See 'Research limitations/difficulties' section below).

3.2 Broad-spectrum of the outcomes

3.2.1 First stage of interviews

Signs of preference of mediation.

During identifying the requirements of KCI found that there is a cultural problem and lack of understanding of ADR.

Justification of focusing on construction disputes resolution in private sector.

3.2.2 Second stage of qualitative interviews

Poor usage of the existing ADR forms.

Having a preference of mediation rather than any other ADR, in order to resolve construction disputes.

Suffers of Lack of awareness in the amicable alternative dispute resolution (mediation).

People in Kuwait need edification of ADR and the benefits of ADR.

Not only workers in the construction industry but the whole public of Kuwait need this type of education, because each individual will be involved in construction of at least their own house.

Important concerns (based on culture) for instance: trust and integrity of “ordinary” third party dispute resolution process.

Specific data analysis, detailed outcomes description and discussion are specified soon, just after the research limitations/difficulties and literature review.

4 ADR not litigation or arbitration

Six interviewees, out of 27 interviews with professionals in construction industry, preferred not to resort to ADR in case of dispute in construction projects and keep the existing applicable route (five interviewees preferred arbitration and only one interviewee preferred litigation). The interviewee (a senior lawyer) who preferred litigation had doubts about the workability of voluntary nature of ADR in Kuwait, as people there do not have the will to use such process and they have got used to adversarial forms of dispute resolution. In addition, the interviewee praised the dignity, integrity and impartiality of the judicial authorities. He added “middle eastern culture trusts judicial authorities, and believes in their integrity and impartiality which makes it too difficult to trust neither a third party nor accepting the idea of ordinary person”. Finally, because this respondent was interviewed in the second stage, he shared some barriers to ADR with other interviewees, which will be discussed later (see barriers to mediation below).

The other 5 interviewees, who preferred arbitration, have not refused ADR because they are not good alternatives to litigation and/or arbitration; their key reason was in preferring arbitration that ‘it is binding’. In other words, they have got doubts to the success of the non-binding processes. However, they have all shown their disapproval

towards the high amount of arbitrators' fees and the long time procedure of arbitration (minimum six months) in Kuwait, which is longer than litigation in some cases. Since (82%) of interviewees agreed on ADR and as the objectives of this paper are to explore and study the barriers to ADR (mediation), so the interviewees who refused resorting to ADR in construction disputes will be neglected for now.

5 Mediation in Kuwait

The 15 interviewees out of 27 (71%) who agreed on ADR, preferred mediation as an alternative to litigation and/or arbitration in construction disputes, which suits the situation in Kuwait due to different reasons (will be discussed soon). Nevertheless, they mentioned some barriers to mediation, which will be revealed later. Another 11 interviewees (29%) were distributed as follows: only one (5%) selected conciliation whereas another five (24%) had no clue what to choose, notwithstanding they have agreed about ADR. However, the five interviewees who did not decide what ADR to choose, they were not able to make a decision because of their lack of knowledge in ADR (see barriers to mediation below).

5.1 Conciliation in Kuwait

Only one expert interviewee selected conciliation because of the involvement of the third party in terms of advising the disputants, this interviewee (a lawyer/ex-consultant) had real concerns about the neutrality of the third party. In which the interviewee preferred to give the opportunity for the independent third party to express their views frankly, so both disputants can discover whether the third party is neutral or not, that was why he have not chosen mediation as the best practice

Furthermore, all interviewees have agreed about the barriers to ADR and they do believe in the same barriers to mediation with believers of mediation. The next section demonstrates the 'raison d'être' of mediation which was presented in the literature reinforced by the interviewees perspectives.

5.2 Why mediation?

Although mediation was preferable in both stages of interviews, detailed reasons of preferring mediation were asked during the second stage of interviews only. That is why only twelve interviewees out of sixteen (who decided that ADR is more convenient than litigation and/or arbitration in the second stage of interviews) will be taking into account for this section. Out of 12 interviewees only nine insisted that mediation is the most suitable form of ADR for construction dispute resolution, one preferred conciliation and two interviewees have not had any clue what sort of ADR to choose. Different factors have been argued by the interviewees (i.e. duration and cost of dispute resolution, different effects of the settlement and the nature of the process and the third party in between).

5.2.1 Shorter time

All respondents insisted that mediation saves parties' time which can be wasted through long process and routine of litigation. Two interviewees, a contractor and a consultant, declared that "actually we are looking for shorter process to settle our disputes", whilst other interviewees' opinion was not far away from that. Four interviewees (an investor, two contractors and an expert) agreed about that arbitration did not achieve the purpose

that it was found for. Arbitration was found to make process shorter and faster, contrary it made it longer, slower and more expensive (the cost will be discussed below).

5.2.2 Cheaper/cost effective

Disputants are always seeking for lower costs to resolve their disputes. An investor confirmed that “Gaining money is what we are working for, and thus there is no reason to waste it in courts”. Although the court’s fees are very cheap comparing with the claim’s amount (0.01% in best cases), the cost of lawyers are too high (50-60% of the claimed amount). In the words of an interviewed contractor “lawyers cost is an extortion”. Two out of three interviewed lawyers objected about the high cost of lawyers and demonstrated that ‘lawyers can be in long-term contract with firms, so they take their disputes with no extra fees, it is just the yearly agreed payment!’ On the other hand, when arbitration produced to be an alternative to litigation, it was meant to be cheaper and faster as mentioned above, but in fact it became approximately equivalent to litigation in terms of cost if not more expensive, however, lawyers agreed with other respondents (100%) about the effective cost of mediation.

5.2.3 Maintaining relationships

Relationships are always an issue in any kind of conflicts. To maintain relationship (either social or business) disputants must show tolerance and forgiveness toward each other and the conflicted case in between. Nine interviewees (all contractors, consultants and investors) have had the potential to waive their rights in the sake of maintaining their relationships with other parties furthermore their reputation in the market, since it is small community. Definitely, lawyers and mediators have not had an opinion in this part simply because they have not got a right to be waived. Yet, all respondents thought that resorting to mediation offered an advantage to the construction industry, in which it keeps the favourable relations between the parties. Moreover, the mediation option preserves the disputants’ reputation between other workers in the industry. Also, mediation can improve the reputation of the parties in some cases, in the sense of they are flexible in emulation to conflicts and do not go extreme in antagonism.

5.2.4 Compromising better deals/flexibility

Negotiating around a dispute most likely gives a better deal, whether parties reached an agreement or they have not. Richbell (2008) insisted that “mediation provides the opportunity for the whole story to be told” wherein disputants will have the chance to listen to each other rather than facing each other in the court or arbitration process. The best deal can be reached while going through litigation process is (Win/Lose) situation, and most likely its (Lose/Lose) situation (Sayed-Gharib et.al. 2010). However, because mediation is not a legal argument, both/all parties can be winners, (Win/Win) situation, since in mediation all of the disputants have to agree and say YES to the deal.

Nine interviewees, who agreed about mediation, concurred that having the negotiation opportunity with other parties, with the attendance of a neutral third party, always gives them more comfortable and stronger position in their standpoint. In addition to that, mediation process could reveal for them their own mistakes, if any.

All interviewees, even the ones who did not prefer mediation as ADR to construction disputes, believed in dealing with the dispute by mediation, definitely, results (Win/Win) situation. Not only money wise, but maintain relationships and keeping

reputation can be accounted as winning matters in the case of mediation succeeding. This confirms that, the interviewees who did not agree about mediation, either did not accept as true that mediation is booming, or they did not understand what is mediation and how does it work.

Parties resort to dispute resolution in order to defend their possessions and rights. Aiming to get hold of the whole rights might cause losses in other sides of the projects itself or parts of the whole organisation. Disputants can share the (Win/Win) position by compromising a solution, assuming that achieving hundred percent solution, (Win/Lose) situation, is impossible by confrontation. 8 of the interviewees granted that mediation is all about compromising a suitable solution, which might not fit most of the disputants' desires, but it is a fair agreed solution.

5.2.5 Non-adversarial

"Move away from adversarial methods" (Ilter and Dikbas 2009) because adversarial schemes in dispute resolution irritated parties in terms of their stability in the market and relationships with other parties. Eleven interviewees believed that their organisations definitely will be effected if they had a case in the court, one of the interviewees described being in court as "a headache". Additionally, number of interviewees preferred, in previous disputes, to neglect their rights rather than going through litigation procedures.

5.2.6 Confidential

Confidentiality is very important issue in construction disputes, since it reflects on the parties' reputations and relations with others. Reputation in construction industry is case sensitive; it can be affected by having many cases in the court, and "in fact libellous nature of litigation may perhaps damage anybody's reputation" said by an interviewed investor in construction projects. Protecting parties' reputation is all about confidentiality of the dispute resolution process. Eight respondents agreed that mediation provides the meant confidential process.

5.2.7 Non-binding

The mediation's agreement is not binding for disputants, unless they have signed an agreement, which allows the disputants to resort to litigation during the process or even after the decision was made (before signing the agreement). The non-binding nature has encouraged six respondents to prefer mediation as a trial to settle their dispute before falling into arbitration/litigation routine. Yes, some interviewees argued that this opportunity can be misused (i.e. to delay the opponent and/or to decrease their chances of winning) but mediation worth trying in which it can save massive efforts.

5.2.8 Voluntary

Although mediation is known as a voluntary process, it has been addressed as an advantage to mediation by only four interviewees in Kuwaiti construction industry. The humble percentage indicates lack of acceptance of voluntary mediation and they do prefer mandatory mediation instead which will be revealed soon.

5.2.9 Neutrality

The neutrality of an ordinary third party, not judicial body, is always a question, however, barely two of interviewees accepted that a well trained third party (mediator) is trustworthy, and these two were mediators no doubt. The low percentage can be considered as a deciding factor to mediation. There is a significant percentage of interviewees show doubt on neutrality of mediators (read doubts on neutrality below).

5.2.10 Summary

Nine deciding factors to mediation (see Figure 1) have been agreed by interviewees, the level of agreement varies due to lack of awareness on mediation, however, the short illustration brief sessions were enough for the interviewees to recognise the appropriateness of using mediation to resolve construction disputes. The deciding factors to mediation in this study were picked up from the general speech with the interviewees as themes, with consistency to the advantages of mediation in the literature. The last three factors, which had results of 50 per cent and less, were faced with some disagreement by number of interviewees. The disagreement will be discussed below as ‘difficulties to use mediation’.

Figure 1: Deciding factors to mediation (advantages)

5.3 Recognition of appropriateness

A huge percentage of interviewees (71 per cent) agreed about the appropriateness of mediation, but due to lack of awareness about it, the usage of mediation was poor in construction disputes. The above mentioned documents conditioned resorting to ADR by certain clauses should be in the contract. Richbell (2008) concluded that ‘just because the contract does not specify mediation, it does not mean parties cannot use it’ parties can always agree to resolve their dispute in any form of dispute resolution, however, mediation or any other sort of ADR must be agreed in due course before it is too late. On the other hand, respondents consented that resorting to mediation, initially, sounds like an easy choice and a smooth process but in fact it is not. There are other difficulties to employ mediation in Kuwaiti construction disputes, these difficulties will be called barriers to mediation. The following sections demonstrate the Kuwaiti perspective upon the barriers to mediation in construction disputes from the interviewees’ experience.

5.4 Difficulties to use mediation

Although the last three (above mentioned) advantages of mediation are common in the literature, and agreed by small percentage of the interviewees but they led the authors to a significant problem toward employing mediation. The data provided indications of difficulties to use mediation. Authors have recognised lack of approval towards ADR due to the lack of acceptance of the said advantages as advantages from large percentage of interviewees, furthermore, some other difficulties to use mediation found during the second stage of the data collection period.

5.4.1 *Binding vs. Non-binding*

Half of the interviewees were encouraged to prefer mediation to its non-binding nature. Despite the fact that 33 per cent claimed that the decision after mediation trail must be binding once disputants agreed to resort to mediation, no doubt, they do not know enough about mediation. Disputants always, not only workers in the construction industry, have got concerns of their opponents' intentions. The rest of the 17 per cent did not have any clue in this regards because of their lack of awareness.

In addition to the above mentioned 33 per cent of the twelve interviewees who agreed about mediation but not it is non-binding nature, there are the interviewees who have chosen arbitration for this reason which rises that percentage to 47 per cent out of the whole set of interviewees. This high percentage puts a question mark in front the non-binding nature of mediation, however, Richbell (2008) insisted that is dangerous to give the mediator the chance to recommend a binding decision for many reasons; the mediator may use or reveal confidential information given by parties, it can destroy the mediator's neutrality for one of the parties or both, and by binding decision of mediator parties abdicate the opportunity of having a (Win/Win) situation because any third party's decision can be, often, (Win/Lose) to one of the parties.

5.4.2 *Mandatory vs. Voluntary*

Only 33 per cent considered the voluntary nature as an advantage to mediation, while 67 per cent thought making ADR compulsory by obligating disputants to go through ADR forms before resorting to litigation/arbitration was important, however, from this huge percentage it seems that ADR got to be a mandatory clause in the contract, not an optional choice, in case of dispute, and this could be one of the causes of limited spread of mediation so far.

5.4.3 *Doubts on neutrality*

Nearly 17 per cent of the interviewees (mediators only) believed in the neutrality of an independent and well trained third party. Surprisingly, 42 per cent of interviewees did show lack of trust in the third party's neutrality neither integrity, on the grounds of that this third party is an ordinary person not judicial body, in addition to that Kuwait is a small country and the opportunities of knowing each other are very high. The rest of the interviewees (41%) did not comment on this part as they are not aware of the situation.

The three above revealed difficulties pave the way for barriers to mediation's widespread in resolving construction disputes of Kuwait. The early findings (barriers to mediation) will be discussed below, in details, in order to diagnose the situation and limitations of employing mediation in the construction disputes.

BARRIERS TO MEDIATION IN KUWAITI CONSTRUCTION DISPUTES FROM INTERVIEWEES PERSPECTIVE

During the second stage of interviews and after discovering, from the first stage of interviews, that the existing ADR process' in Kuwait are rarely used, number of disincentives of implementing ADR were revealed by interviewees in the second stage. The themes of disincentives were categorised based on the redundancy. Two main barriers to employing ADR were shaped; lack of awareness and cultural aspects. Moreover, six different barriers were classified under cultural barriers as the mentioned barriers are well related to the culture.

6 Lack of awareness in ADR (mediation)

6.1 Level of knowledge

Ilter (2009) pointed to the level of knowledge on mediation in the Turkish construction industry, she explored that there is a severe lack of knowledge upon mediation. Although level of knowledge is an important issue, authors discovered from the preliminary interviews that there is major lack of awareness of mediation in the Kuwaiti construction industry. All interviewees, in both stages, (27) were asked about their knowledge or awareness of mediation. None of their responds were out of the following choices:

Don't know about mediation, and need brief explanation about it.

Know about mediation, but not in detail.

Know about mediation fairly, but not used it.

Know about mediation very well, and used it.

They have answered this question as follows in Table (1):

Table 1: level of knowledge/awareness on mediation

Respond	Frequently	Percentage
Don't know about mediation (needed brief explanation session before the interview)	10	37 %
Aware about mediation, but not in detail (procedure and process)	8	30 %
Know about mediation fairly (but never used it yet)	5	18 %
Know about mediation very well (used it at least once)	4	15 %

Although 30 per cent designates the low level of knowledge on mediation, 37 per cent is a significant indicator of lack of awareness of mediation.

6.2 Interest of improving the knowledge and usage

Sixteen interviewees, during the second stage of interviews, were asked about their need and desire to learn more about mediation. The asked questions and detailed answers are discussed below.

Q: If there is an opportunity to learn more about mediation will they go through it? Answers (in Table 2) indicate that 75 per cent have got the desire to improve their knowledge in mediation, which identify the lack of understanding of the mediation mechanism.

Table 2: workers' desire in learning more about mediation

Respond	Frequently	Percentage
Yes	12	75 %
Maybe, if needed.	2	13 %
No	1	6 %
Do not know	1	6 %

6.3 Interest of using mediation

Another question was asked to the respondents about their consideration of using mediation in resolving future disputes. The results are presented in Table 3 which shows that 63 per cent confirmed resorting to mediation in order to settle their construction disputes in future.

Table 3: Future view of resorting to mediation

Respond	Frequently	Percentage
Definitely	10	63 %
Maybe, if needed	3	19 %
No	1	6 %
Do not know	2	12 %

7 Different cultural aspects

All interviewees, in the second stage interviews, agreed about six cultural barriers to ADR (mediation in specific). Certainly, the respondents revealed on signs of the following six barriers (Figure 2 below) while answering about the advantages of mediation. In fact, views are always vary from place to place, there are some factors

which can be addressed as advantages somewhere and can be disadvantages somewhere else, it depends on many aspects (i.e. Culture). So, what can be a deciding factor to use mediation in UK (for instance) can be a barrier to mediation in Kuwait. Below a brief discussion of cultural barriers which revealed by the sixteen interviewees in the second stage:

Figure 2: Cultural barriers to mediation

7.1 Personalising

One of the cultural aspects in construction disputes is taking projects' conflicts personally, in which this conflict turns into a personal conflict. Some interviewees found such an incident as normal human being phenomenon. Ninety three per cent of respondents thought that disputants always take their disputes as personal issues due to the prevailing adversarial methods of dispute resolution. A lawyer suggested that "people always think of revenge if they did not get hold of their desired rights". Disputants always seek justice in addition to the 'winner' feeling, so it is all about righteousness.

Mediation can provide the two above mentioned criteria 'justice and feeling'. Yes it might not be the feeling of 'winner' but it is the feeling of 'satisfied', an investor declared "why should I take it personally if we had a smooth resolution". However, mediation is not widespread actually most people never tried it or even heard about it, they never seen a result to be able to judge on the process abilities. An expert suggested 'Successful practice by influencing famous bodies to be revealed to public' by then people may accept to change their view towards taking disputes as personal issues.

7.2 Signs of weakness

The existing contracts do not contain clauses for ADR which shows proposing mediation, or any other form of ADR, as a sign of weakness. Proposing mediation gives, indirectly, feeling of defeat/victory for both parties. In this case, who offers mediation? This is an important question at the beginning of every dispute. In fact offering mediation in due course is a vital, however, none of the disputants have got the potential to offer resorting to mediation due to their prestige. Precisely, 75 per cent of

interviewees agreed that offering mediation shows signs of weakness to their opponents, it is a common thought. The only found solution for this barrier is to articulate mediation in the contract at the beginning, so mediation will not be an optional choice any more it will become a compulsory in case of dispute.

7.3 Parties' intransigence

Intransigence is a cultural matter; parties in Kuwaiti construction industry sometimes do have the desire to break their opponent. Sixty two per cent admitted that they had this feeling during disputes and thought they could do it by litigation, however, professionals with their long experience have discovered the impossibility of such a desire, elderly and experts suggested this barrier can be eliminated by obligating parties to resort to mediation.

7.4 Concerns of the final decision's effectiveness

While the mediator's decision is not binding for parties, unless an agreement has been signed, parties have doubts of the reaction of their opponent. Fifty nine per cent of the interviewees noticed their concerns of the finality of the decision, a consultant stated "what if we agreed upon a settlement then the opponent felt uncomfortable and took their actions the next day". Clearly, this can be addressed as misunderstanding (or low level of knowledge) of mediation. In fact the decision, of mediation, is binding after signing the settlement agreement; indeed nobody signs such an agreement timidly.

7.5 Concerns of trusting non-judicial bodies

Forty two per cent had doubt in ensuring the neutrality of the third party if s/he was not a judicial body. Three interviewees shared the same sentence "we do trust a judicial third party but not an ordinary third party". Hesitations towards the fairness of a third party came on surface because: low level of knowledge of the mediation process, lack of trained mediators and essential reason is *Kuwaiti judicial body's* Impartiality, as a lawyer in construction disputes insisted. Finding trusted, experienced and well trained mediators is definitely the perfect solution.

7.6 Fear of change

There are always fears of trying something new. Litigation and arbitration are readily available, even if these procedures are not convenient, smooth, slow and expensive. But they feel that they know these procedures very well, there is an old Arabic saying says "*what you know is always better than what you do not know*". Even though the fear of change between workers in the construction industry is 40 per cent and this percentage is not as high as other barriers (see Figure 2) but it should be improved. It seems that the fear came on top almost due to the lack of awareness in mediation, some interviewees suggested helpful solution (i.e. edification and training courses). Although solutions to eliminate barriers are beyond the target of this study but some suggested solution will be discussed below.

8 How to eliminate the mentioned barriers to mediation

As a result, this study paved the way for further studies. Wherein some interviewees suggested new directions for supplementary studies; to eliminate the above mentioned barriers to mediation, and to improve the employment of the existing ADR in Kuwaiti construction industry's disputes:

8.1 Suggested instruments of cultural improvement and edification:

The interviewees suggested different ways to demolish the mentioned barriers. Some of these tools were revealed by other researchers:

Education: (Schools or Illiteracy Centres);

Training courses: (Academic or Coaching) trainings for (Long or Short) periods;

Information: (Books, Booklets, Leaflets, Brochures, Electronics or Internet);

Media: (TV, Radio, Newspapers or Internet);

Practice: (by famous organisations and influential people); and

Events: (Conferences, Workshops or Seminars).

These instruments have the ability to influence the culture and people's awareness.

8.2 Other suggestions to improve the employment of ADR in KCI's disputes

Thirty four per cent of the interviewees agreed that the government must obligate projects' parties to add clauses to the construction contracts in order to force disputants to go through ADR by law. Obligating parties towards ADR was discussed in the literature in different countries. Some researchers found that this approach might affect the voluntary nature of ADR in which does not achieve the goal of ADR (i.e. flexibility), and some other researchers found it as a must for construction contracts due to the massive cost of litigation and/or arbitration and the time overrun in adversarial types of construction dispute resolution.

9 Further discussions and Conclusions

9.1 Mediation in Kuwaiti construction industry and barriers

Although it is not specially designed for construction disputes, a role of mediation exists in Kuwait (see Table 4). Future role(s) of mediation in Kuwaiti construction industry can be considered in further studies. Particularly, while this study focused on the barriers to employing mediation, expectations of exploring future role(s) of mediation would be easier and available.

Table 4: ADR forms in Kuwait

Document name (English)	Provided by	Under (Institute)	Methods discussed	Issued (year)	Usage (based on interviews)
Conciliation and Commercial Arbitration System	Kuwait Commercial Arbitration Centre	Kuwait Chamber of Commerce and Industry KCCI	Conciliation and commercial arbitration	2000	Poor
The Procedural List and The Basic System	Kuwait Lawyer's Association Arbitration Centre	Kuwait Lawyer's Association KBAR	Mediation and arbitration	2004	Very poor
Regulations of Mediation and Optional Arbitration in Engineering Projects	Kuwait Mediation and International Arbitration Chamber - under construction	Kuwait Society of Engineers KSE	Should be mediation and optional arbitration	Under preparation on expected late 2011	N/A

This is an in progress research which aims to substantiate the effectiveness of mediation to resolve construction disputes amicably, neutrally, cost effectively and within shorter duration than litigation. A settlement which keeps reputation of disputants, maintains their social and future business relationships. The above mentioned advantages of mediation were described, by the interviewees, as the deciding factors to mediation.

On the other hand, the interviewees highlighted the lack of awareness and the cultural barriers to use mediation in the construction disputes (i.e. personalising, signs of weaknesses, parties' intransigence, concerns of the final decision's effectiveness, concerns of trusting non-judicial bodies and the fear of change)

9.2 Barriers elimination vs. mediation implementation

Technically, in order to employ mediation as a trail to resolve construction disputes, parties should have agreed to resort to mediation in the case of dispute. The main reason of the pre-agreement is that disputants always feel weakness if they have offered mediation during dispute phase, which makes the agreement upon mediation as dispute resolution process is a must to be articulated as a clause in the contract. Other barriers can be eliminated partially; however, reducing the effect of the mentioned barriers could

take long time especially the cultural aspects. Changing culture considered to be impracticable in short time periods. This ongoing research is intending to discover new ways of removing the barriers to mediation, in sequence to implement mediation in construction dispute.

10 Acknowledgements

This study faced two main limitations; low level of knowledge and lack of awareness on ADR; and the need for independent translation and editing. The authors of this article thank the interviewees for their time and efforts, and the ‘society of engineers’ and the ‘society of lawyers’ for facilitates finding respondents. The authors also are grateful for the anonymous translator and editor of both stages of interviews and the short sessions’ notes, her efforts in both stages are appreciated. Finally, special regards to the proof reader, who finished his task quickly in a record time.

Abstract:

Multilateral Development Banks including the World Bank have identified infrastructure development as a crucial component of any poverty alleviation strategy in developing countries. The last two decades have seen tremendous increase in the percentage of resources developing countries have invested in infrastructure development. About £755 million was committed to private-public infrastructure development in the developing world between 1990 and 2001. Unfortunately, as exemplified by the Dam Construction Project in Lesotho, disputes often arise from major infrastructure projects in the developing world that are resolved at great cost by courts and arbitral tribunals constituted from the most expensive legal professionals in the developed world. This research presents a critical review of the literature on the experience of such disputes and the methods used in resolving them. It derives from the preliminary phase of a study aimed at developing the knowledge and understanding necessary for more cost effective resolution of such disputes. The key findings of the review so far are as follows. What literature exists is limited largely to resolution by international commercial arbitration. As to be expected of the size of these projects, governments or state entities are often parties to the underlying contract and, therefore, the disputes from the projects. In the overwhelming majority cases, the parties from developing countries are often the respondents and rarely the claimants. There is a perception that developing countries are always at a considerable disadvantage in the conduct of arbitration proceedings, which is a source of disaffection with the process on the part of these States. However, what is most remarkable about the literature is that, although there is a rapidly growing use of alternative dispute resolution (ADR) methods other than arbitration to resolve similar disputes in the developed world, the literature is silent on the use of such methods on projects in developing countries. The paper also considers the implications of the findings of the review for the design of the study.

1 Introduction

In 2000, when one hundred and forty-seven heads of States met at the United Nations (UN) Millennium Summit, poverty reduction was high on the agenda (Sachs and McArthur, 2005). Among the goals agreed was to halve those surviving on a dollar a day by 2015. Many of the world's poor are in the developing countries¹. The International Bank for Reconstruction and Development (the World Bank) and the other Multilateral Development Banks (MDBs) have identified infrastructure development (road, water treatment, plants, power generation/transmission plants and irrigation projects) as an essential part of any effective strategy for alleviating poverty in the developing world (World Bank, 1994; Briceno-Garmendia *et al.*, 2004). At the heart of infrastructure development in developing countries are the major construction projects, often dominated by foreign contractors with the State as the main client (Chen *et al.*, 2007). It is usually the case that these projects are funded by MDBs such as the World Bank, and the various regional development banks (African Development Bank (AfDB), Asian Development Bank (AsDB), European Bank for Reconstruction and Development (EBRD) and Inter- American Development Bank (IDB)). The parties involved, the specific economic and political context and the peculiar features of major construction projects make disputes inevitable.

Often, disputes arise from these projects that are resolved by arbitral bodies outside the jurisdictions of these developing countries at great cost and expense to the respective States. It is rather worrying that the citizens of these impoverished states have to bear the brunt of expensive arbitral processes with the concomitant effect of project delivery delays and increased project cost. This research presents a critical review of the literature on the experience of such disputes and the methods used in resolving them. It reports on the early stages of an on-going study aimed at developing the needed knowledge and understanding for efficient and more cost-effective resolution of such disputes. The review is organised into three main sections. The first section briefly examines recent trends in infrastructure development in developing countries and its relationship with the construction industry. This is followed by a critical review of the literature on the resolution of disputes arising from major projects in developing countries. The final section examines the implications of the outcome of the review on the design of the rest of the study.

2 Infrastructure Development and Construction in Developing Countries

2.1 Characteristics of Infrastructure Projects

Infrastructure, in the broader sense of the word, means more than a physical project. It has been defined as comprising the physical facilities, institutions and organizational structures, or the social and economic foundations, for the operation of a society (UNCTAD, 2008). In this research the definition of infrastructure focuses on physical infrastructure. The World Bank (2004) defines infrastructure, in economic terms; as public utilities (power, telecommunications, piped water supply, sanitation and

¹ Developing countries as used here refers to all countries classified by the World Bank as developing economies (low income and middle income economies). More information on the World Bank's classification of economies is available at: <http://data.worldbank.org/about/country-classifications>.

sewerage, solid waste collection and disposal, and piped gas), public works (roads and major dam and canal works for irrigation and drainage) and transport facilities (urban and inter-urban railways, urban transport, ports and waterways, and airports). The World Bank's definition however is steeped in the historical view of infrastructure as "public utilities" and/or "public works". This characteristic of infrastructure is not all-encompassing as there are many infrastructure projects today which do not fit the "public" tag. However, one can agree with the World Bank on the examples of infrastructure projects which were cited in the definition above. Many authors such as Prud'homme (2004) and Kessides (1993) provide similar definitions of infrastructure projects. Facilities such as roads, irrigation projects, dams, power generation plants, transport (airports and seaports) share some common characteristics as infrastructure. The United Nations Conference on Trade and Development (UNCTAD) (2008) list five characteristics of infrastructure. Firstly, they are capital-intensive. Secondly, they often involve physical networks. They also are major determinants of the competitiveness of an economy. Fourthly, in many societies, services associated with infrastructure are thorny social and political issues. Finally, infrastructure projects are relevant to economic development and global integration. Prud'homme (2004) adds that infrastructure projects are capital goods in themselves; they are often "lumpy" and not "incremental"; they are long-lasting and space-specific. He concludes that they often benefit both enterprise and households. To the above, one may add disputes; these projects are often laden with all kinds of disputes which may occur some time between the commencement of the project and its commissioning or even thereafter (Cheung and Yiu, 2007).

2.2 Investments in Infrastructure Projects

As a consequence of their importance and the huge investment required, infrastructure projects have historically been the preserve of States (World Bank, 1994; UNCTAD, 2008; Briceno-Garmendia *et al.*, 2004). As of 1994, developing countries were investing about two hundred billion United States dollars (\$200 billion), amounting to about four per cent (4%) of their national output and a fifth of their total investment in infrastructure development (Kessides, 1993; World Bank, 1994). In spite of efforts by States, much has not changed in terms of the percentage of resources they commit to infrastructure development over the years. UNCTAD maintains that States will need to spend between seven per cent (7%) and nine percent (9%) of their national output on infrastructure if the huge infrastructure gap is to be bridged (UNCTAD, 2008).

In response, many developing countries have opened up the sector, which once was the preserve of the State, to the private sector. Since the 1980s, there has been an increase in private sector participation in infrastructure development across the globe (World Bank, 1994; UNCTAD, 2008). Indeed it is said that with the trend of public-private participation in infrastructure development on the ascendency, about 2500 infrastructure projects in developing countries attracted private sector investment commitment of more than \$755 billion between 1990 and 2001 (Harris, 2003; Kirkpatrick *et al.*, 2006). The increase in private sector involvement in the provision of infrastructure has been attributed to the retrenchment of the State from infrastructure development as a result of inefficiency and inability to expand to meet rapidly growing demands (Harris, 2003). From twenty-one projects involving an amount of about \$11,787 million between 1984 and 1987, private sector investment in infrastructure projects in East Asia and the Pacific rose to 871 projects with total investment amounting to \$135.5 billion between 2000 and 2009 (World Bank, 2010). These projects in addition to investments in existing

projects in the region brought the total for the region to \$181 billion constituting 36% of the total investment in infrastructure with private participation for the period 2000-2009 in developing countries (Park, 2010). According to the World Bank, forty-three out of forty-eight Sub-Saharan African Countries implemented 238 infrastructure Projects between 2000 and 2009 with private participation (PPI) and a total investment commitment of \$ 47.6 billion (Izaguirre, 2010). Added to existing investment, the total for this region was \$79 billion, accounting for about 10% of total investment in infrastructure in developing countries for the period (Izaguirre, 2010). Eight developing countries in the South Asian region implemented 361 infrastructure projects with PPI during the last decade. This constituted 15% of the total PPI investment in developing countries with a total investment of \$174.4 billion (Jett, 2010). Compared to the relatively negligible investment in the 1980s, PPI have seen astronomical increase over the past two decades. Figure 1 shows the global distribution of PPI investment commitment to infrastructure in developing countries by region from 1990 to 2008.

Figure 1: Total investment commitments to infrastructure projects with private participation in developing countries, by region, 1990–2008. (Source: World Bank and PPIAF, PPI Project Database)

From the discussions on infrastructure development so far, some trends can be observed. Firstly, States still remain the primary providers of infrastructure development. Secondly, States since the early 1990s have been more willing to allow private sector participation. This has resulted in billions of dollars of investment commitments in infrastructure development in developing countries. Even with the involvement of the private sector, States still maintain some share or interest in such developments. Where States divest themselves of interest in projects, they still retain regulatory oversight (Kirkpatrick *et al.*, 2004; Kirkpatrick *et al.*, 2006). Finally, the past two decades has seen phenomenal increase in investment in infrastructure by States and the private sector in developing countries.

The reason for the increased investment is, in part, attributable to the perceived impact of infrastructure development on economic development. Many authors have acknowledged the fact that infrastructure development is crucial to economic

development (Canning and Pedroni, 1999; Kessides, 1993; Kirkpatrick *et al.*, 2006; Harris, 2003; Briceno-Garmendia *et al.*, 2004; World Bank, 1994; UNCTAD, 2008; Calderón and Servén, 2010). Research examining the relationship between infrastructure development and economic development identifies a correlation between the two (Sanchez Robles, 1998; Canning and Pedroni, 1999; Tan, 2002; Briceno-Garmendia *et al.*, 2004; Giang and Sui Pheng, 2011). Kessides and Prud'homme have argued that much of the literature on the relationship has been focused on infrastructure capital and not services. To them, infrastructure services should be the main measure of impact of infrastructure development. Kessides argues further that whilst most of these studies are fixated on economic growth, not much is explained about the impact on the welfare of people. Prud'homme asserts, in agreement, that impact of infrastructure development affects both enterprises (economic growth) and households (welfare of the people). His explanation of the linkages is illustrated by him as shown in Figure 2. below.

Figure 2: How infrastructure contributes to development. (Source: Prud'homme (2004).

The provision of infrastructure for potable water, electricity, health and sanitation will directly and dramatically benefit and improve the welfare of households and thereby impact poverty reduction (Briceno-Garmendia *et al.*, 2004). The importance attached to infrastructure makes the process by which they are developed a matter of utmost importance.

2.3 Infrastructure Development and Construction: The Relationship

At the heart of the ever expanding infrastructure in developing countries is the international construction industry. Whether it involves building from the scratch or rehabilitation, infrastructure development involves construction. As a result of the huge capital outlay required many infrastructure projects have been awarded to foreign

construction companies and experts who have the capacity to execute these projects (Chan, 2005). In Africa, for instance, many American, European and Asian construction companies have been involved in infrastructure project construction for decades. A table compiled from Engineering News Record by Chen et al (2007) spanning the period 2001-2005 reveals that American contractors had 15.42% market share of construction projects on the African continent in 2005. Whilst British firms had 5.04% of the share of the market, European contracting firms collectively had 49.33% of the construction market share. In recent years many Chinese construction companies have joined the competition for construction projects on the African continent (Chen et al., 2007). A study conducted into the operations of Chinese construction firms in Africa found that there is a huge increase in the number of Chinese construction firms operating in the region. From the building of soccer stadia and dams in Ghana to the construction of roads in Zambia, the influence of the Asian construction companies is being felt. The Chinese construction firms as of 2005 controlled 21.36% percent of the market (Chen et al., 2007).

The involvement of international construction firms in infrastructure development in developing countries is a global phenomenon not limited to Africa. This has resulted in the emergence of a huge international construction industry with implications for *inter alia* law and dispute resolution. Disputes often arise as a result of land acquisition for the projects, re-settlement of communities affected by projects, employment and labour concerns, health and safety issues or indeed shareholding challenges. In this research however, the focus is on construction disputes and their resolution.

3 Resolution of Construction Disputes Relating to Major Projects

3.1 International Construction Disputes

By the very nature of infrastructure projects as outlined earlier, and the peculiarities of the construction industry whether domestic or international, disputes are bound to occur (Hibberd and Newman, 1999; Gaitskell, 2006). Dispute may arise between clients (who are often States) and designers of the project, in respect of unsatisfactory or poor quality designs; between Clients and main contractors for instance in relation to excess works, unforeseen works or subsequent works (Matijevic, 2008). Issues of quantity and quality, extension of time and claim payment are often associated with such projects. From the ICSID Caseload Statistics for 2011 (ICSID, 2011) geographic distribution of new ICSID Cases registered in 2010 by State Party involved are as follows: Eastern Europe and Central Asia, 27%; Sub-Saharan Africa, 27%; South America, 31%; South and East Asia and the Pacific, 8%; and Central America and the Caribbean, 7%. The sectors affected by these disputes included power generation, transport and construction. These statistics give an indication that many disputes relating to projects involving developing countries are being submitted to international arbitration.

Currently, the perception is that developing countries are spending huge sums of money in dispute resolution across the arbitration centres of this world. Disputes can have very devastating consequences for the contractors and more importantly the clients, whether it is a State or both a State and an investor in a joint venture. Delays can occasion huge cost overruns and retard the progress of other economic activities. It has been found through analyses of large engineering projects that in the areas of arms, petrochemical, energy and power projects cost overruns range between 30% to 700% (Miller and

Lessard, 2000). Whilst these overruns may be attributed to several factors, inflation, and poorly defined contract terms are also cited as causes of such overruns (Merrow et al., 1988 in Miller and Lessard, 2000). The impact may reach far beyond the parties involved. Resource constraint has always been an issue with the developing world. For developing countries, an effective system of resolving such disputes is indispensable. What then are the experiences of developing countries regarding how dispute from major infrastructure projects are resolved?

3.2 Developing Countries and Construction Dispute Resolution

Disputes arising from transactions within a State fall within the jurisdiction of the State and are often tried by national courts. However, with the upsurge of cross-border and international commercial activities, national courts in developing countries have lost their appeal as the preferred choice for settling disputes arising from such transactions (Leahy and Pierce, 1985-86). Domestic litigation has been costly and time-consuming (McLaughlin, 1979). Undeveloped laws, political risk, perceived bias against foreign parties, over-crowded national courts, lack of familiarity of foreign parties to local procedure, lack of confidentiality, forum-shopping, conflict of law complications and issues of enforcement of foreign judgments (Leahy and Pierce, 1985-86; Perloff, 1992; McLaughlin, 1979) are but a few of the reasons which have been advanced in support of a system which can render fair, effective, efficient and final decisions in cross-border transactions (Leahy and Pierce, 1985-86).

International Commercial Arbitration has emerged as a preferred mechanism for dispute resolution in international commercial¹ transactions globally (Ehrenhaft, 1977; McLaughlin, 1979; Al-Baharna, 1994; Leahy and Pierce, 1985-86; Perloff, 1992; Blackaby *et al.*, 2009; Fowler *et al.*, 1980; Cotran *et al.*, 1996). The word “commercial” is often defined to include construction transactions. Features of ICA such as jurisdictional neutrality, its consensual nature, flexibility in procedure and process generally, confidentiality (Ehrenhaft, 1977), reduced cost, speed and party autonomy have made it suitable for the emerging global system of commerce which have parties from different countries, cultures and legal systems (McLaughlin, 1979; Perloff, 1992).

The development of ICA in developing countries can be examined from two perspectives; legal developments and institutional developments. In respect of the former, two international instruments have been crucial; the Convention on the Recognition and Enforcement of Foreign Arbitral Awards, 1958 (the New York Convention) and the United Nations Commission on International Trade Law (UNCITRAL) Model Law on ICA. The main objective of the New York Convention has been to commit States who signed on to it to give effect to agreements to arbitrate and to enforce within their territories foreign arbitral awards which satisfy certain agreed criteria for validity and legitimacy². The possibility of enforcement of a binding arbitral award not just at the seat of the arbitration but also internationally has endeared ICA to the international business community. Currently, 145 countries are parties to this

¹ See the notes accompanying the United Nations Commission on International Trade Law (UNCITRAL) Model Law on International Commercial Arbitration, 1985 (as amended in 2006). It suggests that the word “Commercial” be interpreted broadly to include all matters arising from relationships of commercial nature. The list provided as part of the note include construction of works, consulting, engineering, and investment.

² See Article III of the New York Convention, 1958.

treaty¹. Even in Latin America, a region noted for its support of the Calvo doctrine², it is reported that all countries within the region have signed on to the Convention as of 2003 (Bernal, 2009). The UNCITRAL Model Law on International Commercial Arbitration, 1985 (as amended in 2006) on its part, aims at eliminating the inadequacies of national laws and disparities between them. To this end it sets out special procedural regime for international commercial arbitration³. Currently, about sixty countries, many of them developing nations, have adopted local arbitration legislations based on the UNCITRAL model.

Beyond these global efforts, there have been regional efforts to develop the law on international arbitration. For example, the Organization for the Harmonization of Business Law in Africa (OHADA), an international organization set up by treaty in 1993, with sixteen mainly West and Central African francophone member States, aims at harmonizing business laws among member States. As part of its activities it has adopted a uniform Arbitration Act, set up a court, and developed its own arbitration procedures.

International arbitral institutions in Europe have served as venues for ICA between many developing countries and foreign entities. The role of national courts in international commercial arbitration has been ancillary. Arbitral institutions such as the International Court of Arbitration of the International Chamber of Commerce, the London Court of International Arbitration, and the International Centre for Settlement of Investment Disputes (ICSID) in particular, have arbitrated hundreds of cases between private entities, States and private entities and between States for several decades. In relatively recent times, other arbitral institutions have been set up in Hong Kong, Singapore, China, Dubai, Cairo and Nigeria to serve Asia and Africa. The African-Asian Legal Consultative Committee (AALCC) has been very instrumental in the effort to ‘regionalise’ arbitration centres (Asouzu, 2001; Asouzu, 2006; Sempasa, 1992). AALCC’s efforts led to the setting up of the regional centres in Cairo and Nigeria in Africa and in Kuala Lumpur and Tehran in Asia. The rationale is to bring ICA closer to countries in Asia and Africa.

Generally, very little exists by way of literature on ICA in developing countries as compared to the developed world. The little literature relating to developing countries identified so far have revealed that ICA remains the dominant resolution mechanism in all commercial transactions (Cotran *et al.*, 1996; Asouzu, 2001; Blackaby *et al.*, 2009; Tiewul and Tsegah, 1975; Sempasa, 1992). Virtually all standard form contracts governing construction transactions in developing countries, notably those published by the International Federation of Consulting Engineers (FIDIC) contain provisions on ICA (Tackaberry and Marriott, 2003). It is stated that the dominance of the use of ICA has created “a *de facto* universality of it as the normal method of dispute settlement and parties sometimes choose it without much thought as to its suitability to the circumstance”. (Tackaberry and Marriott, 2003). For Latin America however, ICA has not been the popular choice. Many Latin American countries until recently have insisted on subjecting international transactions taking place within their jurisdictions to national

¹ See the New York Convention, 1958, Status of Parties. Available at: http://www.uncitral.org/uncitral/en/uncitral_texts/arbitration/NYConvention_status.html. Accessed on 18th May, 2011 at 11:30am.

² This doctrine essentially insists on “the non-intervention and absolute equality of foreigners with nationals” in dealings by States with foreign nationals.

³ See notes accompanying the UNCITRAL Model Law, 1985 (as amended in 2006).

judiciaries. This practice, deeply ingrained in their constitutional practices, take its roots from the Calvo doctrine (Bernal, 2009). However, the trend is gradually shifting to international commercial arbitration (Bernal, 2009).

What literature exist thus deals generally with ICA without any specific treatment of how it operates in the context of international construction disputes relating to major projects. The focus of the literature has been on the challenges posed by ICA to developing countries (Yelpaala, 2006; Asante, 1993; Asouzu, 2001; Sempasa, 1992). These challenges can be divided into the generic and the peculiar. Key issues under the generic category are cost and delays (Asouzu, 2001). Regarding cost, disputes arising from major infrastructure projects are often resolved at great cost to developing countries whose citizens are made to bear such expenditure eventually. A good example of this is the case relating to the construction of the Katse Dam in Lesotho. The facts of the case are aptly set out in the opinion of the English Supreme Court (then, the House of Lords) in *Lesotho Highlands Development Authority (Respondents) v. Impregilo SpA and Others*.¹ In 1991 (after a sixty year preparatory period), the Lesotho Highlands Development Authority engaged a consortium of seven companies from the United Kingdom, South Africa, Italy, Germany and France to construct the Katse Dam in Lesotho. The contract was made on 15 February 1991 under standard FIDIC Conditions of Contract (4th edition) with terms and additions. The contract was governed by the law of Lesotho. After the conclusion of the project in 1998, the Contractors made a claim for reimbursement of increased costs and for upwards adjustments to prices and rates. The dispute was eventually referred to Arbitration in London under International Chamber of Commerce (ICC) rules as provided for by the contract after the Engineer's decisions on the claims were rejected. The decision of the arbitrators was also appealed to the Supreme Court.

The focus of this reference is not on the substance of the claims. What is worrying however, is the fact that Lesotho, a small landlocked developing country with human development index ranking in 2007/2008 of 138 out of 177² had to spend resources on registration fees, administrative expenses, counsel's fees, arbitrator's fees and expenses, witnesses expenses, court, travelling, accommodation and feeding expenses for local representatives and lawyers to pursue the above-described dispute. For a developed economy, the impact of the cost may be negligible. The situation with a developing economy is however different. It may be argued that such cost may be recovered eventually if the State wins the "contest". This however is not always the case as parties often do not recover their entire cost.

UNCTAD, in a related study on the issue of cost in investor-State arbitrations (UNCTAD, 2010) has found that the cost of arbitration generally has increased drastically. Whilst legal fees constitute about 60% of the expenses, the arbitrators' fees, the administration fees of arbitral centres, expenses of witnesses and experts also constitute substantial cost. Referring to previous UNCTAD reports (UNCTAD 2005b, 2006a, 2008a and 2009) the report cited four cases as examples. In *Plama Consortium v. Bulgaria*³, the legal cost for the claimant amounted to US\$4.6 million whilst that of the respondent amounted to US\$ 13.2 million. In the second example cited, the claimant

legal cost in *Pey Casado v. Chile*¹ relating to the jurisdictional and merit phases of the arbitration amounted to US\$ 11million, whilst that of the respondent amounted to US\$ 4.3 million. In *ADC Affiliate Limited and ADC & ADMC Management Limited v. The Republic of Hungary*² the respondent country had to pay US\$7.6 million in legal cost. Finally, in *Waguih Elie George Siag and Clorinda Vecchi v. The Arab Republic of Egypt*³, the respondent was obliged to pay an amount of \$6 million as legal costs, expert and other expenses.

Though relating to investment, these examples are not far-fetched. Many international investment agreements define investment to include, “claims to money and claims under a contract having a financial value”(UNCTAD, 2011). Indeed, international construction transactions and disputes share some common features with Foreign Direct Investment (FDI) and investment disputes. Firstly, the clients involved in international construction transactions in developing countries are often Sovereign States. The decisions which may be challenged by an international construction firm are decisions taken by the State or its agencies. Often, whilst the State will prefer that its courts resolve disputes arising, the Contractor on the other hand will be wary to have a matter involving the State tried before its own courts. The amounts involved in these transactions are huge. FDI and investment disputes share these attributes. The issue of the rising cost of ICA is a common attribute. The confidentiality of these arbitral processes sometimes make it difficult to obtain figures on cost. However, for both developed and developing countries and indeed even investors (UNCTAD, 2008), cost of arbitration has been an issue.

Regarding delays, ICA was reputed for its swiftness (Ehrenhaft, 1977). However, this feature of ICA has been questioned as cases take more time to resolve (UNCTAD, 2010). Indeed, one author has described ICA as a highly complex commercial litigation (Oh, 1981). Though this description is dated, it remains true. Nearly all the procedural complexities associated with a court proceeding can be found in most arbitral hearings involving huge projects. The consequences of these are delays. The impact of delays on project delivery and increased project cost is hackneyed, and particularly severe on developing countries.

The second category of concerns with ICA relate to those peculiar to developing countries. Asouzu (2001) draws attention to some factors in the current international regime for dispute resolution which are causing serious disaffections in the developing world. He mentions that there is a perceived bias against African States and by extension, other countries in the developing world in the international dispute resolution process, enforced by the relationship between the World Bank, a major lending institution for most of them, and the International Centre for the Settlement of Investment Disputes (ICSID). This perception, he asserts, is further fuelled by the following factors: absence of African arbitrators on arbitration panels in the West; the fact that in nearly all cases involving African States or companies, they often are the respondents and hardly the appellants; the choice of American and European venues or arbitration centres over equally well established ones in Africa, for example those in Cairo and Lagos; and the long-standing arguments of lack of judicial infrastructure, qualified personnel and fair hearing which are still maintained without any basis. He

¹ ICSID Case Number. ARB/98/2

² ICSID Case Number ARB/03/16

³ ICSID Case No. ARB/05/15

concludes on the note that while staying the current course, African arbitration centres and governments need to publicize the current wave of change in the industry in Africa (English, 2002).

Asouzu's recommendations focused on regionalizing arbitral centres and awareness creation, but were relatively passive and bland in relation to the development of alternatives such as mediation, dispute boards and establishment of dispute early resolution systems, which may be crucial to the international construction industry especially at the initial stages of a conflict. On the absence of African arbitrators on arbitration panels, articles 12 to 16 of the Convention on the Settlement of Investment Disputes between States and Nationals of Other States (ICSID Convention), 1966, for example, provide that member States are allowed to designate four qualified persons to be part of its panel of arbitrators and panel of conciliators respectively. Beyond the ICSID situation, most Arbitration Rules permit parties to nominate an arbitrator, whether the requirement is for one or three arbitrators. Again it may be argued that often, developing countries end up selecting arbitrators from the developed world, and thus can not probably turn around and raise concerns about their own choices (Asouzu, 2006). The reality on the ground however, as conveyed by the ICSID case load statistics (ICSID, 2011), is that Africa and many developing countries still have a lean presence on the ICSID arbitration and conciliation panels.

Characteristically, the existing literature focus generally on ICA with no specific attention paid to the construction industry per se. This is so whether at the national (Cotran et al., 1996) or regional level (Asouzu, 2001), with the exception of a few from the Asian region where some efforts are being made to examine international construction disputes distinctively (Cheung and Suen, 2002; Chau, 2007; Chan and Chan, 2002; Chan, 2005a; Chan and Suen, 2005; Chan, 2006; Chan, 2005b).

Two conclusions have emerged from the literature so far. First, the literature existing on resolution of infrastructure disputes in the developing world are generic in nature and deal with international commercial arbitration generally. There is dearth of literature dealing specifically with construction disputes arising from major infrastructure projects and the processes involved in their resolution. Secondly, there is a huge knowledge gap in relation to what transpires immediately a dispute arises and when formal ICA process commences. Whilst one may look up to the dispute clauses in the various standard form Construction contracts for an answer, those answers are merely theoretical as what pertains in practice may differ drastically. No empirical evidence has been found on the issue. As the story of Adjudication in England has shown, good early dispute mechanism(s) of interim or permanent nature, prior to arbitration may be useful for the construction industry in developing countries. Incipient disputes may be nipped in the bud should there be a clearly existing system which parties can resort to prior to International arbitration. Further, the materials so far reviewed do not consider in detail the viability and the role that alternative dispute resolution mechanisms can play in resolving such disputes. These emerging conclusions have implications for the design of the research as next discussed.

4 Research Design

What type of research approach will be suitable for the kind of enquiry envisaged? It is submitted that a qualitative / an interpretivist approach is best suited for this kind of research for several reasons. Firstly, the subject-matter of the research- dispute resolution- is a social phenomenon which occurs in a real world setting. Secondly, the views of participants in major infrastructure projects are crucial to our understanding of the complexities associated with the extant dispute resolution mechanisms. Thirdly, apart from being heavily context-based, the phenomenon under study has not been explored. Further, the appropriate instruments required in studying complex human interactions such as efforts parties make or steps they take pending ICA proceedings must be those which offer some flexibility in terms of administration on the field. This accords with the social constructivists or the interpretivist view of research (Berger and Luckmann, 1967; Lincoln and Guba, 2000). Most of the major treatises on research design, such as the *Handbook of Qualitative Research* (Denzin and Lincoln, 2005), point towards a qualitative research approach being most appropriate for research with the types of features outlined above.

Qualitative research offers various approaches for data collection and analysis. Ethnography, Phenomenology, Grounded theory (Corbin et al., 2008), the biographical method, Narrative Research (Creswell, 2009) and Case Study (Yin, 2009; Stake in Denzin&Lincoln,1998; Flick,2006) are all qualitative strategies of enquiry. It has been stated that where there is a need for an in-depth investigation into a contemporary phenomenon in its natural context, Case study may be the appropriate strategy of enquiry (Yin, 2009). Yin adds further that case study research is useful where the aim of the research, among other things, is to explain, explore, or describe an intervention in its natural setting. He argues that in making a choice between case study and other social science strategies, consideration should be given to the research questions to be investigated and the type of study envisaged. If the enquiry is about “how” and “why” some social phenomenon works, and extensive and in-depth study envisaged, then case study will be a good choice of strategy.

An in-depth study of the extant dispute resolution system for disputes arising from major projects, the gaps in the system and possible remedial strategies for all developing countries is not feasible in this research. However, an in-depth study of the situation in a typical developing country sharing common attributes with the rest will make vital contribution to knowledge, which *mutatis mutandi* will be informative and useful to the others (Flyvbjerg, 2006; Yin, 2009). This type of study raises a number of challenges; sample or case(s) selection, the theoretical implications of a context-based study, issues of verification and generalizability. The subject of the choice of a case(s) and the complexities that go with such a venture have been discussed by authors (Eckstein, 1975; Achen & Snidal, 1989; Flyvbjerg, 2006; Gerring, 2007; Collier and Mahoney, 1996; Stake, 1995; Seawright and Gerring, 2008; Yin, 2009). It is expected that this research will examine these challenges and their impact on the plausibility of the research design envisaged.

5 Conclusion

The importance of infrastructure development to poverty reduction and economic growth in developing countries cannot be over-emphasised. Substantial resources are currently being invested in projects in developing countries by both States and the private sector. Crucial to the provision of infrastructure is the international construction industry. With its peculiar features of multiple parties, varied works, quality and quantity of work and issues relating to payment among others, disputes are bound to occur. The literature related to developing countries point to international commercial arbitration generally as the main dispute resolution mechanism. Gaps have been identified in respect of; (1) the absence of specific study relating to resolution of construction disputes arising from major projects; and (2) the absence of empirical evidence on what transpires between the time disputes arise and when the processes of international commercial arbitration commence. The phenomenon to be studied is context-based and to fully appreciate it, the views of participants are required. Due to lack of previous exploration of the field, an in-depth study will be more useful. This makes qualitative study the preferred approach and case study, the preferred strategy of enquiry. However, other research approaches are likely to be considered for their suitability as new evidence emerges. It is expected that the outcome of the study will be useful not only to the case studied but also other developing countries.

Asset, property and facility management

Promoting Energy Efficiency in Public Sector Commercial Buildings in Australia

Clive M J Warren¹ and Simon Huston¹

¹Business School,
University of Queensland, Brisbane Qld,
Australia

Email: c.warren@uq.edu.au

Abstract:

The State and Federal Governments in Australia have sought to lead by example and significantly reduce the energy consumed in public sector buildings. A number of reporting and benchmarking schemes have been developed, over the past two decades, to encourage and require property and facilities managers to reduce energy consumption and the emission of greenhouse gases. This paper investigates the process employed to implement savings and analyses the reported outcomes of the schemes both in terms of public sector savings and in influencing private sector behaviour. The paper will also look at recent legislative changes in Australia which mandate the measurement of energy use and greenhouse gas emissions by private sector owners and occupiers yet specifically fall short of including public sector assets within the reporting requirements. Implications of this legislation on the management of both public and private sector buildings will be evaluated.

Keywords:

Australia, energy efficiency, office, sustainable building management,

1 Introduction

The cost of energy and its impact in terms of contribution to the emission of greenhouse gases has long been recognised by the Australian Government. This paper will track the development of government policy over more than two decades and will evaluate the outcomes of those policy decisions on the efficiency of the public sector asset management strategy which implements the energy saving initiatives.

There is wide global recognition of the potential adverse effects of climate change and the Australia Government has been a strong advocate for adaptation of our industry to meet the challenges which increasing levels of CO₂-e will have on the earth's climate. Australia recognises that with less than half a per cent of the world's population, it contributes around 1.5 per cent of total global greenhouse gas emissions. Even before the UN Rio Declaration the Australian Federal Government had begun a systematic reduction of its energy consumption across its property portfolio having recognised that energy use represents 95% of the governments greenhouse gas emissions, targeting building energy consumption was seen as a valid target to achieve savings.

The Brundtland Commission Report in 1992 and its definition of sustainability which was endorsed by the 1992 UN Earth Summit in Rio became a catalyst for change. The Earth Summit culminated in the global agreement within the Rio Declaration and Agenda 21 which requiring all member states to develop a national sustainability development strategy (UN 1992). The practical application of these stated sustainability goal gave further impetus to the government's energy policy.

The early recognition that buildings play a major role in contributing to CO₂-e emissions has over the years been recognised by many researchers with estimates of the role which buildings play worldwide accounting for somewhere between 40% and 70% of global energy consumption, and have a resulting carbon footprint significantly exceeding those of all transportation combined (WBCSD 2009; McDonagh 2011). Thus there is considerable focus placed on the building management and development sectors to reduce energy consumption. The WBCSD (2009) see buildings as: 'Large and attractive opportunities to reduce energy use at lower costs and higher returns than other sectors.' These are recognised as fundamental to achieving the International Energy Agency's (IEA) target of a 77% reduction in the planet's carbon footprint against the 2050 baseline to reach stabilised CO₂ levels called for by the Intergovernmental Panel on Climate Change.

2 Literature Review

The Australian Federal Government in October 1990 introduced a policy to reduce greenhouse gas emissions. This policy included a number of initiatives designed to improve energy efficiency in government buildings. The main features of this policy were:

- the appointment of energy managers in government departments and authorities;
- the annual reporting by government departments and authorities of energy use and energy efficiency improvement initiatives undertaken;
- the establishment of, and adherence to, high standards of energy efficiency in the construction and leasing of Commonwealth buildings;
- energy management training;
- the use of Commonwealth buildings for demonstrations of energy efficient technologies; and
- the establishment of a database of Commonwealth energy use. (ANAO 1996)

In July 1992 the Government Buildings Energy Audit Program (GBEAP) was launched for all Commonwealth occupied owned and leased buildings. The program provided funding for energy audits of Commonwealth buildings. Later in the same year the Prime Minister announced that; 'using 1992-93 as a base year, departments and budget funded agencies would reduce energy use in Commonwealth occupied buildings by 15 per cent before 1998-99 and by 25 per cent before 2003-04' (ANAO 1996).

The Australian National Audit Office, which has a management overview responsibility to the parliament, undertook a detailed evaluation of the government's energy management policy in 1992. This audit reviewed the management of energy in both owned and leased Commonwealth buildings. The audit estimated the cost of energy in

Commonwealth buildings at that time to be in the region of \$258 million per annum. The report also estimated that there was the potential for savings in the region of between \$29 million and \$46 million per annum. The audit made twenty-six detailed recommendations for the implementation of savings measures across the portfolio (ANAO 1992). These recommendations included requirements for agencies to report on energy consumption and efficiency the report also found that the Department of Primary Industries and Energy (DPIE) had no formal plan for implementation of the government's energy efficiency targets which had been previously set. These recommendations were restated in a further audit the following year of the Department of Administrative Services which at the time was responsible for the management of all owned and leased commercial buildings (ANAO 2003).

One of the primary recommendations of the 1992 Audit Report was the requirement that departments should publish their energy use and energy efficiency improvement initiatives in their annual reports to government. Changes were made to the Guidelines for the Preparation of Departmental Annual Reports with specific energy management reporting requirements implemented (ANAO 1992). This reporting regime was altered for the reporting year 1993-94 when the Department of Primary Industries and Energy assumed responsibility for the collection of this data from all agencies. This change was criticised in a follow-up audit undertaken in 1996 when ANAO stated 'Since then DPIE has instituted alternative mechanisms to collect this data but the ANAO found that the data is often late, varies in quality and excludes important information and may or may not cover budget dependent agencies' (ANAO 1996).

The ANAO 1996 report concluded that that progress on the implementation of the Government's energy management targets by DPIE had been 'slow and inadequate' in that 'savings targets, are unable to be measured because of the paucity of performance information' (ANAO 1996). This follow-up audit made a series of recommendations regarding improved reporting and data collection by DPIE.

With a change in government a new energy efficiency scheme was announced in 1997 the Government's greenhouse gas emissions policy, was another initiative aimed at improving energy efficiency in Commonwealth operations. The policy established agency energy use targets which were to be achieved by 2002-03. Details of the scheme released in 1998 established a number of requirements for agencies to meet. Key among these was a requirement that agencies meet energy use performance targets in which all agencies were to ensure that all commercial office space owned or leased meets Commonwealth energy use performance targets by 2002-03. These standards are:

- 10 000 mega joules per person per annum energy use target set for office buildings tenant lighting and power;
- 500 mega joules per square metre per annum target set for office building central services.

In addition requirements to undertake further energy audits of office building and to meet energy guidelines for all new buildings were also introduced (ANAO 2002).

The follow up audit of 2002 reported that agencies had made good progress in implementing the recommendations of the 1999 Audit Report recommendations and

that the 2002-03 energy efficiency targets set by government in 1997/98 were likely to be met before the 2002-03 reporting year with respect to tenancy level light and power consumption (ANAO 2002)

The 1997 policy Measures for Improving Energy Efficiency in Commonwealth Operations was superseded in 2006 by the updated policy Energy Efficiency in Government Operations (EEGO) which remains the current government policy and the objectives against which all government departments are mandated to report (Australian Greenhouse Office 2006). The key aims of this policy were to achieve a 25% reduction in energy intensity for office tenancy light and power use and a 20% reduction in energy used by central services. These reductions are over and above the 1997 targets as these were no longer seen as providing an incentive for continuous improvement and more challenging targets were required to increase savings (Australian Greenhouse Office 2006).

The new energy intensity targets aimed at achieving 7,500 MJ/person pa, for tenancy light and power and 400 MJ/m²pa for central services. In addition it introduced a requirement that all new tenancies over 2,000m² should meet the Australian Building Greenhouse Rating (ABGR) 4.5 star rating. ABGR has subsequently been incorporated into the National Australian Built Environment Rating System (NABERS) and taken over by the New South Wales Government. The 2006 policy also recognised that to achieve energy savings in central services of leasehold property, that cooperation with the landlord would be necessary. The policy thus launched a Green Lease Schedule, a document which clearly articulates the energy saving goals of government and which was intended to form minimum green lease requirements in any new leasehold agreement.

The Federal Government having established a clear policy directive and reporting mechanism which tables a consolidated energy report in parliament each April and publishes these results both in a written report and in data spread sheet format.

In order to further expand the energy saving objectives of central government and to link these with a number of similar policies developed by each of the State and Territory Governments a meeting of the Council of Australian Governments (COAG) in July 2009 developed a policy document 'National Strategy on Energy Efficiency.' This strategy document outlined a large number of initiatives to reduce greenhouse gas emissions across a number of industries not just the public sector. With respect to owned and leased government buildings the strategy set objectives for developing a national reporting framework and to establish national benchmarking and green lease standards across all jurisdictions. Currently each state and territory sets their own benchmark standard, although all currently have a minimum NABERS standards as shown in Figure 1.

	NABERS Energy	NABERS Water	NABERS Waste	NABERS Indoor Environment

Figure 1 Government Minimum NABERS Rating

It is not possible to make direct comparisons between the NABERS rating of a building and the Federal Governments 2006 target based on MJ/person pa. or indeed the central services target of 400 MJ/m² pa. as the NABERS methodology includes a number of undisclosed correction factors which weight different regions of the country utilising a benchmarking factor, in addition the measurement of area of the building does not follow the same definitions used in general lease agreements or the EEGO policy which uses Net Lettable Area (NLA) as the basis of measurement. The star rating awarded under NABERS is a measure of environmental impact and a relative assessment against other properties within a region and as such is not a direct measure of energy consumption.

It is not possible for example to place the Federal government targets within any individual NABERS rating and it is thus not possible to show that if an individual building archives the desired rating set out in the state and territory targets shown in Figure 1 that the building would also meet the EEGO policy targets. Indeed a brief analysis of the published NABERS Star ratings for a variety of buildings show a wide range of results in terms of MJ/m² for a base building rating. A base building NABERS rating measures central plant energy consumption and is broadly similar to the central services definition contained within the EEGO Policy (Australian Greenhouse Office 2006; DECC 2010). The range of results shown for individual commercial buildings located in major Australian cities show that for a five star NABERS rated building the base building energy intensity is typically in the range 200 MJ/m² to 400 MJ/m² although some building have energy intensity figures in the early four hundreds. A four star building falls in the range of 300 MJ/m² to 500 MJ/m² but individual buildings with figures as high as 740 MJ/m² are evident in the results. Three star properties fall in a range between 407 MJ/m² and 850 MJ/m² with most in the middle of this range. What is evident from these figures is that the star rating under NABERS is not an energy

intensity rating it is, as it states a measure of greenhouse gas emissions. Thus any comparison between the EEGO policy targets and the NABERS targets is not practical as the energy intensity target of 400 MJ/m² set in 2006 could conceivably be achieved in anything from three to five star rated building.

3 Research Methodology

The data for this study is made freely available by the Department of the Environment, Water, Heritage and the Arts in its annual reports. Government departments are required to provide their energy use data together with space use and employee numbers in order for the whole of government reporting to parliament to be undertaken. This research project has collated published data since reporting year 2003/4 in order to enable analysis of the portfolio performance. In addition the data is also analysed to permit comparison on a per square meter basis as well as permitting benchmarking between departments on the basis of employee numbers.

The Federal Government data is then compared with publicly available data published on the NABERS website in order to compare the stated energy intensity of government buildings with a sample of those in the private sector.

4 Energy Intensity Data

The Department of the Environment, Water, Heritage and the Arts (DEWHA) which is charged with management of the EEGO policy collates data from across the Federal Government portfolio and publishes an annual report on progress against the policy objective. The most recent report for the period 2007-2008 states, with respect to the office portfolio, that a reduction of five per cent was achieved on the previous year with respect to tenant light and power and a four per cent improvement was achieved in central services. The average results across the entire portfolio saw the average reach 8,113 MJ/person/annum for tenant use and central services was at 461 MJ/m² a (DEWHA 2009). The report goes on to predict that both of the EEGO policy targets could be met by June 2011.

The data reported to government at an agency and portfolio level, which is used to compile the annual DEWHA report is made publicly available and allows a deeper evaluation of the government portfolio of assets and analysis of the outcomes of the energy targets. In analysing this data the focus is on the office estate as this has the most bearing on the wider economy and serves as a benchmark against which the private sector can measure itself. Thus in this analysis the defence portfolio is excluded as are properties other than office use.

In analysing the available data the first issue which becomes apparent is that the size of the public service has significantly increased since the government targets were established in 2006. In 2003/4 the government portfolio under review comprised 2.3million m² of office space in which 109,868 staff were employed. Four years later the area of office occupied had grown by 22.4% to 2.8 million m² of office space with a corresponding 27% increase in occupancy to 139,598 people. Figure 2 below shows the growth in area occupied and occupancy across the government portfolio. Along

with an increase in office space there is inevitably an increase in the central area which grew by 25% over the period.

Figure 2 Office Area and Occupancy 2002-2008

While the occupancy and area occupied has significantly increased the energy intensity of the central services has decreased marginally over the period having initially increased in 2005/6 the energy intensity is now at a level 2.8% below the 2003 figures but remains 43 MJ/m² above the target rate.

Figure 3 shows the change in central services energy intensity over the period.

Figure 3 Portfolio Central Services Energy Intensity

In order to achieve the target rate of 400 MJ/m² the portfolio will need to make a further 10% reduction over and above the 2007/08 year results.

A similar picture exist for the energy intensity in terms of tenancy light and power on a per occupant rate.

Figure 4 shows a similar pattern of increase in the period 2004/05 and then a steady reduction over the three periods between 2005 to 2008.

Figure 4 Portfolio Light and Power Energy Intensity per Occupant

The total reduction over the study period is just 7.24% and the energy intensity still remains almost 500 MJ/m² above the target level of 7,500 MJ/m². In order to achieve the target a further 6% saving will need to be achieved.

This analysis on a portfolio wide basis clearly shows that the introduction of the government policy has had a positive outcome in terms of savings in energy intensity over the period and the government is on track to meet its target by 2011-2012.

5 Conclusion and Further Research

The Australian Federal Government has pursued a policy of energy reduction within its office portfolio for over two decades. During this period of time there have been several changes of government and realignment of ministries responsible for implementing energy policy. This paper has documented the history of this policy objective and Australian Government's commitment to reducing energy consumption and consequential CO₂-e emissions to the atmosphere. The research has shown that through mandating target energy intensity levels government has managed to achieve the goals established and demonstrated its ability to reduce its carbon footprint. In reducing the energy demand government has not only made significant cash savings and reduced CO₂-e emissions it has also been able to demonstrate to the wider community that significant energy savings can be made within an office portfolio.

The positive outcomes of this government policy are having an effect on the wider property industry. The federal government in 2010 legislated in order to require a greater level of energy transparency in the private sector. All office buildings over 2,000m² are now required to display a NABERS rating when leasing or selling office space. While the scheme is being phased in from November 2010 to full implementation in November 2011 there has already been a significant increase in the numbers of buildings seeking to obtain a NABERS rating for their buildings in order to comply with the legislation. The likely outcome of this will be a greater focus on energy saving in order to attract tenants or investors in office proper.

The Federal Government has also been able to work with the State Government's in order to encourage their greater participation in energy savings and sustainable office use. This has led to work being undertaken to establish a national energy benchmarking process for all public sector office buildings. This joint initiative will have even greater influence on the public sector both in demonstrating how savings can be achieved and also in ensuring that any owners seeking to lease office space to the public sector meet minimum sustainability criteria.

The Netherlands

Email: a.straub@tudelft.nl

Abstract:

Obtaining information on reliable service lives of building products is of great importance when completing environmental life-cycle assessment (LCA) reviews, for life-cycle costing (LCC) and for maintenance planning tasks. In the Netherlands a catalogue for the reference service lives of building components exists since 1995. The catalogue covers all common building components and building services.

There is a lack of reliable reference service life data of building products. All available international service life databases are not in accordance with criteria for reliable data, set down in the ISO 15686-series dealing with service life planning. In the Netherlands a review of the existing service life catalogue was made by expert judgements. The experts expressed a lot of objections to use the factor method for deriving mathematically a bandwidth of estimated service lives of a building product from the reference service life of the product. However the factor method described in the ISO 15686 series offers good opportunities to take the project or design specific situation of building products into account. Generic data about the service lives of building products can be tailored to specific project circumstances by describing the factors and underlying criteria, and the reference in-use conditions.

Keywords:

factor method, life-cycle assessment, life-cycle costing, maintenance planning, reference service lives

1 Introduction

Obtaining information on reliable (standardised) service lives of building components and products is of great importance for, amongst others, building owners, designers and consultants when completing environmental life-cycle assessment (LCA) reviews, for life-cycle costing (LCC) or whole-life costing (WCC), and for maintenance planning tasks. Other reasons to obtain reliable service life data are the development of national and international standards and legislation (e.g. the Construction Products Directive of the EU and Environmental Product Declarations), and new procurement routes like PPP and PFI.

For maintenance planning purposes one has to know the service lives of the building components. If replacements cycles are known, the financial forecast can be made. This financial forecast for maintenance is of great importance for service life planning and life-cycle costing of new buildings and (renovated) existing buildings.

Life-cycle costs are the costs of an asset or its parts throughout the life cycle, while fulfilling the performance requirements (ISO 15686-5: 2008). Generally these are the cost for construction (including design and engineering), operation (including energy), maintenance and end-of-life (disposal and demolition). Life-cycle costing and whole-life costing methodologies are increasingly being used to compare new design and redesign alternatives. In refurbishment irreversible decisions with major consequences for the costs in the use phase, for example cleaning, maintenance and energy, are made too. In new procurement routes performance requirements instead of descriptive specifications are being used and operating and maintenance risks of built assets are transferred from clients to contractors. Working with performance requirements necessitates the provision of reliable information about alternative building products, including technical specifications with indications of service life and performance over time (Trinius and Sjöström, 2005). Reliable data about service lives of building component may reduce the calculated risk by the contractors.

Life-cycle assessment (LCA) can be used to quantify the contribution of building activities to environmental effects (ISO, 1997). LCA should concern the entire life cycle of the assessed product (ISO, 2004). In an LCA study, the effects that the production, use and disposal of products have on the environment are calculated. In construction the environmental effects are determined by first making an inventory of the flow of all substances to and from the environment over a building's complete life-cycle (e.g. Blom *et al.*, 2010). Each substance's potential contribution to pre-defined environmental effects is calculated. In order to do this, for each environmental effect, the impact of a particular of substance flow is compared with that of a reference substance, a process that is referred to as the 'impact assessment'. The quantified effects are usually abiotic depletion, global warming, ozone layer depletion, photochemical oxidation, human toxicity, fresh water aquatic eco toxicity, terrestrial eco toxicity, acidification and eutrophication. The complete set of environmental effects is known as the 'environmental profile'. Klunder and Van Nunen (2003) provide some solutions for including the factor time, including technical service lives of building products, in building LCAs, e.g. by sensitivity analysis.

The lack of reference service lives of building components and products led the Dutch Building Research Institute (SBR) in the 90s of the last century to the publication of a service life catalogue of often applied building products (Huffmeijer *et al.*, 1998). This catalogue gives reference service lives of roughly 600 building products. Data was gathered from various sources and judged by experts. Only service lives were included on which consensus was reached by these experts. One average technical service life of general building products is given. Specific attention is given to needed interim maintenance. An update of the data was considered since.

To make the life-cycle cost calculations and the outcomes of LCA-studies more robust and to estimate the risk of shorter and longer lifespans of the building components a research project was set up to answer the following research questions: (1) What are

reliable service life data of current used building products, and (2) How can generic data about the service lives of building products be tailored to specific project circumstances? To tailor the generic data the 'factor method' described in the ISO 15686-series Buildings and constructed assets – Service-life planning – (ISO, 2000) has been used. The second research question is made operational in the question how the factor method practically can be used to take into account specific in-use conditions of building components.

2 Research methodology

The research methodology comprised a literature review and expert meetings. The experts were appointed by a research steering group, constituted by the Dutch Building Research Institute, the Ministry of Internal Affairs, the Government Buildings Agency, The Ministry of Defence Support Command Real Estate, and scientists. The eight experts are working at universities, consultancy firms and large property owners. They cover all disciplines of real estate and building products and materials (timber, roofing, masonry, building services) and are well respected in their discipline.

In the first place service life data of building products collected by standardized verifiable procedures in different countries and the use and criticism of the factor method in other countries (UK, Germany, Italy, and France) was analysed, based upon a literature review and contacting scientist in these countries. In the second place ways to use the ISO 15686 methodology were explored during expert meetings. The experts were also asked to judge the (reference) service lives of the building components expressed in the existing catalogue of 1998.

Finally the service life data of building products will be part of the National Environmental database that is being established to standardise the data for environmental life-cycle assessments used in environmental assessment tools (e.g. BREEM-NL). In 2011, industry organisations for building materials and products will value all the data of the National environmental database, including the service lives.

3 Literature review

3.1 Reference service life

Generally three forms of service lives of built assets are distinguished: functional, technological and economic (e.g. Van Nunen, 2010). The technical service life is the only service life that is tied to a building product or component. A functional or economic service life is defined by other influences, for example the society (the demand for a product), or the price of fuel (Van Nunen, 2010). Therefore if the reference service life of a building product or building component is mentioned, it is the technical service life. The ISO standard 15686 defines the reference service life (RSL) as the service life that a building or parts of a building would expect (or is predicted to have) in a certain set (reference set) of in-use conditions (ISO, 2000). In addition is the estimated service life (ESL) the service life that a building or parts of a building would be expected to have in a set of specific in-use conditions, calculated by adjusting the

reference in-use conditions in terms of materials, design, environment, use and maintenance.

3.2 Service life prediction

There are different methods to gather reference service life data: long-term testing, accelerated testing and analytical models. Analytical methods for service life prediction assume that all factors in quantitative terms are known and that the relationships between the influencing factors or processes can be described in mathematical models. Fundamental and empirical research that make use of standard test models is needed to develop these models (see e.g. Daniotti and Re Cecconi, 2010; Shohet and Paciuk, 2004). Several EU-funded international research projects were conducted on durability, service life models and service life prediction of building materials and components, e.g. LIFETIME (see Bamfort, 2005) and EUROLIFEFORM (see Kirkham *et al.*, 2004). ISO 15686:2 (ISO, 2001) gives a systematic methodology for service life prediction. Daniotti and Re Cecconi (2010) give an overview of test methods for service life prediction.

3.3 Environmental Product Declaration (EPD)

Reference service lives are often provided by the manufacturers of building components. In the near future they are obliged to provide these data to be used in Environmental Product Declarations (EPD) (CEN, 2010). Here a relationship with the ISO 15686-serie is being made: “RSL information to be declared in an EPD covering the use stage shall be provided by the manufacturer. The RSL shall refer to the declared technical and functional performance of the product within a building. It shall be established in accordance with specific rules of European product standards and shall take into account ISO 15686-1, -2, -7 and -8. Where European product standards provide guidance on deriving RSL, such guidance shall have priority.” (CEN, 2010).

4 Service life data of current used building products

4.1 Criteria

The aim of the SBR was to use data sources that meet the ISO 15686 standard. The ISO standard gives the following criteria to the data records (ISO, 2008):

- general information;
- scope (including purpose);
- material /component;
- methodology;
- reference in-use conditions;
- degradation agents;
- critical properties and performance requirements;
- reference service life;
- data quality;
- reliability of data;
- additional information considered;
- references.

The ISO standard also gives the rules for validation of data sources that are not fully in accordance with the standard. Depending on the quality of the data source, a laborious process with more extensive research and validation by experts has to take place.

4.2 Available databases

Although the whole range of research initiatives systematic international data records of reference service lives of building components hardly exist. Some take the used materials as a reference, others the compounded building products.

The availability of RSL data of building products that already meet the ISO standard criteria is very limited. For reliable data at least the methodology, the reference in-use conditions and the critical properties should be clear. A complicating factor is that the conditions and properties in one country valuated as being 'normal', might for a another country is not normal at all.

In Germany some limited databases exist, without any information about the reference-in use conditions and the properties (e.g. IEMB, 2009). Especially service life data bases in the UK are meant for contractual liabilities and insurance purposes, e.g. the HAPM Component Service Life (HAPM Publications, 2003) and the Building services component manual (Building Performances Group Limited, 2001). The research centre CSTB of France and the Research Group on Durability of Building Components of the Polytechnic of Milano is establishing a French-Italian database for reference service lives of building components, based upon the ISO standard (Daniotti *et al.*, 2010).

The UK Life Expectancy of Building Components; Surveyors' experiences of buildings in use (BCIS, 2006) meets some of the ISO criteria but not all. A list of generic components (over 300), used in normal conditions was presented in a questionnaire to surveyors who are experienced in inspections of existing property. The results are based upon 92 respondents. They were asked for the average or typical life span, and the minimum and maximum lifespan of building products. Assumptions that they examiners had to take into account were:

The components are installed according to instructions of the supplier or best practices (this is partially verifiable in practice, if visible).

The components meet the requirements of installation and use.

The components are subject to average exposure.

The components are maintained according to instructions of the supplier or as directed by trained personnel.

Although the methodology of this UK database looks very sound, a number of problematic issues related to expert judgements remain, like the unknown experience of the surveyors with the building products and for instance their geographical location. They were not asked for statements about the causes for a shorter or longer life, but only the life expectancy. Unfortunately it lacks clear statements for interim maintenance

The comparability with the Dutch situation of conditions and properties for (part of) construction seems problematic. The SBR decided to take the existing publication as the starting point.

4.3 New Dutch service life database

The publication provides service lives of 600 general building products, which is an average based on given assumptions. In practice, the service life of the building products will be around this average with a certain distribution. The average service lives of building components and products are the best available estimates made by the group of experts. The service life of many structural parts are determined by the experts at least 100 years. Recorded service life data concerns substructure and frame, external walls, upper floors and floor finishes, roofs and roof finishes and window and external doors.

Paints are not included as separate products. Paintwork is an activity necessary to maintain the life of a large number of construction groups in external walls, and windows and external doors. Compared to the existing catalogue internal components, fittings, sanitary appliances and building services were left out. Table 1 gives an example of the data records.

Table 1. Example of service lives of building components: Flat Roof Coverings
(Source SBR, 2011, forthcoming)

		RSL
Metals	Steel, trapezium, galvanized, coated	50
	Steel, trapezium, galvanized	15
	Aluminium, folded, enamelled	60
	Aluminium, folded, coated	40
	Copper, folded	75
	Zinc plates, 10% overlapping	25
	Zinc	40
Bitumen Felt	APP 2-layers; stuck	25
	APP 2-layers; mechanical	25
	SBS	25
Synthetics	PVC-foil	25
	PVC 1-layer; clued	25
	PVC strips; mechanical, overlapping 8%	25
	EPDM 1-layer; clued	25
	EPDM, SBS-cached; mechanical	30
	EPDM membrane; mechanical	30
	POCB strips	25
	POCB; mechanical	25
Divers	Green roofing (moss) on bitumen felt	40
	Green roofing (moss) on EPDM	40

5 Practical application of the factor method

5.1 Factor method

The factor method modifies reference service lives by factors to take account of the specific in-use conditions. “The factor method does not provide an assurance of a service life: it merely gives an empirical estimate based on what information is available. It is different from a fully developed prediction of service life.”(...)“Certain parties involved in building projects may be concerned about liability for forecasting future performance. For the avoidance of doubt, the recommendations of this part of ISO 15686 are not intended to implement contractual liabilities and the expectation is that “best efforts” will be applied, but that forecasts cannot be expected to always be either accurate or precise.”(ISO, 2000). The factors are:

- A. Quality of components;
- B. Design level;
- C. Work execution level;
- D. Indoor environment;
- E. Outdoor environment;
- F. In-use conditions;
- Maintenance level.

The factor method offers the possibility to make a correction of the reference service life using the factors and criteria. Each factor has the default value 1.0. An effect that leads to life extension results in a value greater than 1.0, lifetime shortening gives a value lower than 1.0. Factor values less than 0.8 or greater than 1.2 imply that the chosen reference service life (RSL) is not suitable and should not be used (ISO, 2000). The factor values are determined by the underlying criteria. For each factor several possible criteria exist. The factors are multiplied giving the estimated service life (ESL). In a formula: $ESL = RSL * a * b * c * d * e * f * g$.

The obtained ESL is focused on a specific situation. This allows for a building to indicate specific influences. Two identical products, applied at different locations or otherwise used, will also get a different lifespan. The key is to know the situational factors (which does not involve incidents) and value them. If the situation is similar to the described principles of the RSL, the value is 1.0 and the reference service life (RSL) and the estimated life (ESL) are equal.

5.2 Shortcomings of the factor method

The experts expressed doubts about applying the factor method. The most important are:

- the factor method is not intended to determine the service life of a product. The availability of reliable data RSL precedes knowing the bandwidth of the ESL. To know the RSL of building products a lot of (longitudinal) research has to be executed (See ISO, 2001 and ISO, 2006);
- the RSL of each building product has a certain unknown bandwidth;

the question is whether the factors can be expressed in numbers. The attention points can be mentioned, but they are difficult or impossible to quantify;

the question is whether the factors themselves can and should be multiplied. The (value) factors may be interdependent;

questioned is the use of the method and described factors for building services.

In Germany some similar shortcomings of the factor method were detected. Bahr and Lennerts (2010) say that the ISO 15686 does not give any information on reference service lives or the values of the factors. The proposed German model does give statements with regards to the application of reference service life parameters. They suggest also to differentiate between primary and secondary influencing factors. The values of the influencing factors are, opposed to the ISO, restricted in the new model, enhancing transparency and significance. To minimize the subjectivity of the factor method, The French-Italian database contents grids, that will drive users in choosing the right values of each factor according to the context conditions in which building components are placed (Daniotti and Lupica Spagnolo, 2008; Daniotti *et al.*, 2010).

5.3 Factors and criteria

It was chosen to make a practical application of the factor method that meets the concerns expressed and that makes a connection to international research into service lives of building products possible in the future. The factor method described in the ISO 15686 series offers the possibility of using a reference service life of a building product and seven correction factors to take the project or design specific situation into account. The factors are classified into properties and inherent performance level, in-use conditions and stages. The described reference situation, gives the most common construction practice used in the Netherlands. Deviations from the reference situation will result in a longer or shorter estimated service life of the building product. Figure 1 shows how the estimated service live of a building component could be deduced from the reference service live.

Figure 1. From RSL to ESL

5.3.1 Properties and inherent performance level

The properties and inherent performance level of the building product determines whether the required or desired performance can be achieved. The reference service lives of specific building products are based on the properties and inherent performance level of these specific building products. If another product alternative is being applied belonging to the same group of building products without notice of the reference service life of this alternative, one has to judge the properties and the inherent performance level compared to the known one. One has to think about the resistance to deformation, durability, stability and sensitivity for aesthetical, mechanical, biological agents and degradation, and sensitivity for incorrect use.

5.3.2 Indoor climate

The life of building products used indoors are subject to the conditions of the indoor climate. See Table 2. The average Dutch indoor environment is the basis assumption: a relative humidity between 30-70%, with no external sources of moisture present. The indoor humidity can not only be displayed in a percentage, it also has to do with time of wetness and variations therein. The reference is that temperature ranges between 15 and 25° C and that the temperature fluctuations are limited. In the reference situation there are no contaminants in the air. The air velocity is within 'acceptable limits'. Assumed is ample opportunity to ventilate, so no favourable environment for biological agents is formed and fungi will not occur.

Table 2. Factors and criteria Indoor climate

Criteria	Specification
Humidity	Extent, variations, condensation, rising damp, cold bridges
Temperature	Air temperature, variations
(Chemical) substances	E.g. CO ₂ , carbon, chlorine
Air flows	In relation to pollution
Biological agents	Presence and preventing agents
Light	In relation to discoloration and aging

5.3.3 Outdoor climate

The life of building products used outdoors are subject to the conditions of the outdoor climate (Table 3). The soil can affect the life of certain components (foundation, walls). Basic assumptions are that no (extreme) variations in the soil occurs and the absence of external stresses. If extremes in humidity and temperature occur, may this negatively affect the life of the product. E.g. frequent variations in temperature can (by swelling and shrinkage) may reduce the service life. Shelter of the project by for instance trees, can prevent for extreme temperature changes.

Table 3. Factors and criteria Outdoor climate

Criteria	Specification
Humidity	Duration, variations, associated with the building orientation
Temperature	Air temperature, variations, shelter
(Chemical) substances	E.g. CO ₂ , soot
Biological agents	Presence and preventing agents
Soil	Variations
External load	Vibrations from nearby (rail) roads, factories etc.
Light	In relation to discoloration and ageing

5.3.4 Building function and use

The building function and use may shorten or extend the service life of the building products (Table 4). The reference is that a building product is applied according to the requirement of the manufacturer or supplier. This means for instance that building products for applications in public buildings have such properties, expected that the building products will be used very frequently. Application of this product in housing means a longer life. Also frequent variations in load can, if the building product as required by manufacturer or supplier is not explicitly taken this into account, negative effect the longevity. The basic principle is that loads are more or less continuous and practically no overload occurs. The reference is based on proper use and no vandalism.

Table 4. Factors and criteria Building function and use

Criteria	Specification
Intensity	Building function, private / public, commercial / residential
Loads	Variations, overload
Type of use	Incorrect, vandalism

5.3.5 Design

Building products are selected during the design stage (Table 5). Determined is how products are exposed during their lifetime. The positioning of the building component may be positive or negative. The reference is a 'normal' position for the product. A frame, for instance, is always part of a wall exposed to the elements. If the frame is strongly affixed inward (e.g. an indoor balcony), the estimated service life will be longer. Specific details and the presence of many connections with other components, can be negative for the life of the product. The reference assumes that the construction product is accessible for the necessary maintenance. Another assumption is that the

materials used in the selected building product are compatible with the materials adjacent to the building product. Think of galvanic corrosion of metals.

Table 5. Factors and criteria Design

Criteria	Specification
Positioning	Exposure, shielding from weather, drainage, orientation, height
Detailing	Connections
Provisions for maintenance	Accessibility, space to work
Material compatibility	Suitability of the (combination) of materials
Dimensioning	Construction, subdivision, excess

5.3.6 Execution

The production of the building can affect the life of the building product. See Table 6. The reference is production on site. Production methods such as prefabrication meaning production under controlled conditions, may increase the life of building products. To ensure that implementation occurs as previously thought, the execution takes place according to rules (processes, procedures and instruments). These rules do not guarantee, but encourage to ensure quality. In particular for the management and maintenance stage it is important to record any changes to the design and used materials and products. The reference is that the registration is made. Another reference is a limited exposure to the elements before installation. The products are delivered ‘just-in-time’ or being stored protectively.

Table 6. Factors and criteria Execution

Criteria	Specification
Production	Prefab, in situ, working conditions, method of execution and exposing during execution
Discipline regarding execution rules and skills	Quality systems, supervision performance, competences, expertise and experience staff
Tracking changes	Register (for maintenance)
Transport and storage on site	

5.3.7 Maintenance and management

Maintenance can be of great influence for the service life (Table 7). Reference is a well maintained building. This involves planned preventative maintenance, such as lubricating moving parts, cleaning and paintwork, and planned interim replacements of building parts with a shorter lifetime than the entire building product. Assumed is

proper preventive maintenance and corrective maintenance, carried out according to maintenance instructions. The reference is that spare parts remain available.

Table 7. Factors and criteria Maintenance and management

Criteria	Specification
Maintenance planning	Implementation of preventive maintenance on schedule
Discipline regarding maintenance rules and skills	Quality system maintenance contractor, supervision performance, quality of materials, competences, expertise and experience maintenance staff
Tracking changes	Register of maintenance
Availability of spare parts	

6 Conclusions

More knowledge about the service lives of building products is desired for environmental and economic reasons: for reliable environmental life-cycle assessments and life-cycle cost calculations.

There is a lack of reliable reference service life data of building products. All available international service life databases are not in accordance with criteria for reliable data, set down in the ISO 15686-series. In the Netherlands a review of the existing service life catalogue was made by expert judgements. In the near future, a data format according to ISO 15686-8 should be used by suppliers of building products to declare the service lives of their products and the reference in-use conditions and critical properties. This data could be combined with data by property owners and managers, consultants and surveyors, etc. in accordance with ISO 15686-7. Especially the Dutch Governmental Buildings Agency will do further research to the service lives of building services.

There are a lot of objections to use the factor method for deriving mathematically a bandwidth of estimated service lives of a building product from the reference service live of the product. However the factor method described in the ISO 15686 series offers good opportunities to take the project or design specific situation of building products into account. Generic data about the service lives of building products can be tailored to specific project circumstances by describing the factors and underlying criteria, and the reference in-use conditions.

European research communities should co-operate to develop an international service life database of building components and to address the factors and underlying criteria for service life estimation. The factors and criteria have to be placed in each national context.

Abstract:

The study assessed the practice of do-it-yourself (DIY) maintenance as a means of improving housing stock in Lagos state. The study identified the factors influencing and militating against the practice. In achieving the set objectives, the study adopted research survey technique. A total of 300 questionnaires comprising 160 for owner-occupiers and 140 for tenants were administered for the study. The population was selected from fifteen (15) local government areas in Lagos state, based on stratified random sampling technique. Data collected were analysed using descriptive and inferential statistics. The findings of the study revealed that the factors influencing the practice of do-it-yourself (DIY) maintenance are; to provide a habitable environment, to retain the performance of facilities amongst others while the factors militating against the practice are; jobs involving special skills, health and safety issues, lack of technical know-how amongst others. The hypotheses postulated reveal that there is an association between the factors influencing the practice of do-it-yourself (DIY) maintenance by the owner-occupiers and the tenants. There is also an agreement between the factors militating against the practice as perceived by the owner-occupiers and the tenants. Based on the findings, the study recommends vocational training for building users, building products should be user's friendly, provision of DIY manual for products and tools that will facilitate the practice amongst others.

Keywords:

built-environment, DIY, do-it-yourself, habitable, user friendly

1 Introduction

The state of disrepair of housing and its auxiliary facilities in Lagos state is a concern to both the government and individual citizenry. Adenuga (2002) states in his assessment on built environment revealed that many publicly and privately owned buildings are in various states of disrepair and dilapidations. High proportions of residential buildings in Lagos are dilapidated resulting to increased slums. To meet up with the Millennium

Development Goals endorsement of “cities without slums” before the year 2015, proactive measures have to be embraced. Housing maintenance strategy has to be put in place in order to control the menace caused by slums in our cities today. For a building to retain its functionality and value throughout its life cycle, it must be well cared for through maintenance. Hence housing maintenance strategy to be adopted should involve the direct participation of building users.

Maintenance as a concept refers to all works relating to repairs, replacement and or redecoration performed on any building with the aim of increasing the useful economic life, enhance its value as well as promoting its beauty and functionality and preventing damage and injury (Olatubara and Adegoke 2000). Maintenance, according to Bello (1994) is the entire endeavour to keep physical facilities – structure equipment, machinery and services at a satisfactory level of technical performance and quality of the lowest total cost. Odudu (1994) sees maintenance with respect to building and their services as a continuum of the construction process. According to him, the level of maintenance governs the health of a building throughout its life cycle. Therefore, maintenance involves the total package of all activities taken in caring for a building and all its facilities and services in a state to continue to perform its intended functions to the benefits of the end users, owners and the environment.

Although, there are different types of maintenance outsourcing applicable in maintaining housing stock with factors that determine their applicability. But this study focus on do-it-yourself (DIY) maintenance which involves the direct engagement of the buildings users to tackle minor maintenance and improvement work issues in the home. The aim of the research is to assess the determinant factors of the practice of do-it-yourself (DIY) maintenance approach as a mean of improving housing stock while the objectives of the study is to identify the factors influencing and militating against the practice of the system in improving housing stock in Lagos state.

2 Do-It-Yourself (DIY)

The perusal of academic research works does little to help basic understanding of what specifically counts as DIY. ‘DIY’ crops up in references repeatedly in relation to fields such as law, health and IT maintenance, or in relation to anti-corporate counter culture. Across different fields of activity the term is used to refer to people providing for themselves services which they could otherwise (be expected) to pay a professional to do. However, as reflected in dictionary definitions, the term conventionally refers specifically to accomplishing home maintenance or modification tasks without the paid services of a professional.

3 Factors that Determines the Practice of Do-It-Yourself (DIY) Maintenance Activities

The nature of who carry out DIY is determines by various factors. Viby Mogensen (1990) highlighted the following variables as income, status in the labour market, type of occupancy, gender, age, marital status and life cycle category region and degree of urbanization. Gronau (1977) stated that substitution between white and black labour, leisure and DIY is thought to depend on wages, taxation, and the cost of working and

DIY productivity. The change in time, over geographical regions as it affects differences in hourly wage rates, explains the inclusion of geography as a variable.

3.1 Household Composition

Bogdon (1996) finds household composition as a major determinant of the likelihood of a household taking on DIY. With multiple adult households most likely to undertake it, single parent families the least likely, as well as finding that, people are more likely to take on a contractor where projects are of larger scale, complexity or risk. Baker and Kaul 2002, highlights the significant relationship of changes to household composition with the likelihood of home remodelling. Munro and Leather (2000) explore homeowner's accounts of why they take on specific home maintenance and improvement tasks, which was due to the problem of the declining condition of the British housing stock despite increasing home ownership.

3.2 The Role of Age and Marital Status

The older people get, the less likely they are to carry out minor repairs and maintenance or improvements in their own home (Brodersen, 2003). Marital status here defined as being married or cohabiting, as opposed to being single. Married / cohabiting people are more likely to carry out minor DIY than single people. Also having children does not have a statistically effect on major DIY, and does not increase the likelihood of using DIY for major home improvements and alterations according to Brodersen, 2003. Pollakowski (1988) also agrees that age affect DIY. Davidson & Leather, (2002) pointed out that the older heads of households especially; those over 75 were much less likely than average to carry out DIY work, and much more likely to make exclusive use of contractors.

3.3 Leisure

Mintel (2005) claimed that over a quarter of adults claim to enjoy DIY with 8% identifying DIY as a hobby. The report puzzles over why people prefer to spend time on the labours of DIY rather than more obvious leisure pursuits, highlighting that it exists as a leisure activity even for those able to afford to employ someone else to do the work.

3.4 Self Satisfaction / Pride

Keat and Abercrombie (1991) found a complexity in DIY when people clearly have the means to employ a contractor, but feel that the employed person may not be able to achieve the distinctive and innovative solution to which they aspire and which they can achieve their selves.

3.5 Gender

According to Brodersen (2003) in Denmark and Norway, there are no significant differences between men and women's about the practice of minor DIY. However, in Great Britain with regard to minor improvements and alteration, men specify significantly more DIYs than women do. However, in most studies there is a strong male dominance in minor repairs and maintenance (Flood 1990; Smith 1986). Male-Female differences have been reduced in both DIY activities and household work during the last decade according to Flood and Grasjo (1995).

3.6 Income

According to Brodersen (2003), income has no importance for the likelihood of carrying out DIY activities in Great Britain, and the correlation is only statistically certain at the 10% level in Norway for minor DIY. In Denmark, income is significant for major DIY, and in Sweden for both minor and major DIY. In these countries, the likelihood of carrying out minor and major DIY increases with income, while the opposite is true in Germany, where the likelihood of carrying out both minor and major DIY declines with income (Brodersen, 2003). Williams (2004) identifies a traditional assumption in retail studies to be that DIY is a rational response to an inability to pay for external labour, essentially fitting the model of rational consumer. Pollakowski (1988) finds a complex relation between income and the likelihood of a household undertaking DIY. According to Davidson and Leather (2002), in terms of income, poorer households were more likely to use a contractor and less likely to use DIY, while for higher income groups the position was reversed.

3.7 Occupation and Education

Soren Pedersen (2003) stated that it is precisely skilled workers or people with a vocational education who contribute most to the black economy in Denmark, Sweden, Norway and Germany. Ploug (1990) found that the short term unemployed men spent three hours more a week on repairs and maintenance than other males, while unemployed women spent slightly less time on these activities than either employed men or women.

Brodersen (2003), stated that apart from Germany, education in itself has no effect on the likelihood of minor DIY. That in Germany, people without vocational training are less likely to carryout minor DIY, while people who have gone to technical college are more likely to compared with people who have acquired their vocational training in a firm.

3.8 Unemployment

Obviously, the higher the unemployment is, the higher the incentive to be engaged in DIY activities. Unemployed people have less money for purchasing goods and services and therefore a higher incentive to engage in DIY activities. Additionally, DIY activities may enhance the unemployed's self-esteem, thereby further stimulating DIY activities.

3.9 Tools and Materials of DIY

According to Watson and Shove (2005) DIY stores are increasingly good at helping the consumer, or researcher, understand in what relations particular commodities might become useful. A basic problem in DIY retail is that the majority of products have multiple potential uses. Therefore, it is impractical to display products together to form the ensemble needed to realise a project. DIY economic is growing, there are number of ready-made kits of parts for common projects, such as putting up a shelf, including materials, fixings and instructions in a single pack. Information boards and free 'how to' leaflets highlight lists of 'what you need' together with an outline of the practical steps involved in affecting a particular project. DIY outlets are responding to long-standing criticism by increasing the expertise and availability of staff, not least to be able to advice on the constituent parts of a project. In providing such information according to Waston and Shove 2005, DIY stores are also making available, to some extent, other essential components of a DIY project, seeking to instil on consumers some of the basic

competence and confidence to take it on. Retail spaces themselves therefore reveal the practical relationality of the usefulness of the products they sell to be useful, most products have to be situated in proper relation, to other products, the materials and structures of the home, the competencies and capacities of the DIY practitioner and so on.

3.10 Competence

Campbell (2005) stresses that skill; knowledge and judgement need to be brought to the processes of craft consumption. Leadbeater and Miller (2004) place the satisfaction of acquiring skill and knowledge as one of the central attractions of 'pro-am' pastimes including serious DIY. Davidson and Leather (2002) stated that, in terms of socio-economic group, skilled and professional workers were more likely to use DIY or mixed arrangements and less likely to use contractors.

4 Research Methodology

To achieve the aim of the study, a survey research approach was selected. A structured questionnaire was designed as an instrument for data collection from 300 respondents. The data collected were analysed using both descriptive and inferential statistics. Mean score was used to rank the determinant factors as they affect the practice of DIY in Lagos state. While regression analysis was used to test the hypotheses to establish if there is an association between the factors influencing and militating against the practice of do-it-yourself (DIY) maintenance by building owner-occupiers and the tenants.

5 Analysis of Data and Discussion

5.1 Characteristics of Respondent's

According to table 1, 160 (53%) of the respondents were owner-occupiers while 140 (47%) were tenants. Majority of the household head were male with 75.3% and the female counterpart 24.7%. The household head age limit was mostly above 40 years (55.3%), followed by those within 30-40 years old. Household head within 0-10 and 10-20 years old had percentage of 0.7 and 3.0 respectively. Financial income of most of the respondents was above N50,000 per month while 4.7% had a monthly income within N5000-N15,000. Family size i.e the number of household of respondents within 2-5 and 5-10 had 150(50%) and 103(34.3%) respectively. Respondents that occupied single rooms, a room and living room and duplex had 12.7%, 22.7% and 14.3% respectively, while 48% occupied flat apartments and just 2.3% occupied mansion. 46 (15.3%) of them were classified to be in high social level and 12.3% and 72.3% were in low and average social level respectively.

Table1. Characteristics of Respondents

ITEMS	FREQUENT	PERCENTAGE
Types of occupant		
owner-occupier	160	53.0
Tenant	140	47.0
Gender		
Male	226	75.3
Female	74	24.7
Age Limit		
0-10	2	0.7
10-20	9	3.0
20-30	42	14.0
30-40	81	27.0
40 above	166	55.3
Monthly Income		
5,000-15,000	14	4.7
15,000-30,000	47	15.7
30,000-50,000	70	23.3
50,000 above	169	56.3
Family size		
0-2	22	7.3
2-5	150	50.0
5-10	103	34.3
10 above	25	8.3
Apartment occupied		
single room	38	12.7
Room and living room	68	22.7
Flats	144	48.0
Duplex	43	14.3
Mansion	7	2.3
Social Class		
Low Class	37	12.3
Average Class	217	72.3
High Class	46	15.3

5.2 Determinant Factors that Influence the Practice of DIY Maintenance

From table 2, building owner-occupiers agreed that to make facilities remain functional (3.32), provision of a habitable environment and acceptable standard (3.30), minor maintenance jobs that can easily be tackle by them (2.98) and self satisfaction (2.95) were the major reasons why they DIY in their homes. In addition, issues like time and emergence reasons for repair of faulty facilities (2.80), availability of DIY tools and products (2.78), reduction of home maintenance cost (2.85) and competence of using DIY tools and products (2.84) were also agreed on as factors that influence their desire to practice the system. The tenants agreed that provision of habitable environment and

acceptable standard (3.22), making facilities remain functional (3.11), minor jobs that can easily be tackled (2.77) and self satisfaction (2.76) were DIY practice motivating factors.

Table 2: Factors influencing the practice of DIY maintenance
(Source: Field Survey 2010)

Determinant factors that influence the practice of DIY maintenance	owner-occupiers		Tenants	
	Mean	Rank	Mean	Rank
Habitable environment and acceptable standard	3.30	2	3.22	1
Makes facilities remain functional	3.32	1	3.11	2
Minor jobs that can easily be tackle	2.98	3	2.77	3
Self satisfaction	2.95	4	2.76	4
Time and emergence reasons since faulty facilities have tobe repair immediately	2.80	7	2.72	5
Availability of DIY tools and building products	2.78	8	2.65	6
Save money and reduced maintenance cost	2.85	5	2.59	7
Technical know-how of using DIY tools and equipment	2.84	6	2.55	9
Technical knowledge of installation or removal of build- ing products	2.68	11	2.57	8
High labour charges of skilled workers	2.69	10	2.48	10
Availability of information on DIY products and tools from the manufacturer	2.72	9	2.40	13
Degree of enjoyment and fun	2.68	11	2.41	12
Job involving special skills	2.66	13	2.45	11
Building maintenance rules and regulation	2.63	14	2.36	14
Leisure time activities and pleasure at home	2.59	16	2.32	16
Strength and ability to carry-out the activities	2.62	15	2.25	18
Law enforcement agencies and avoidance of fine charges	2.58	17	2.23	19
Interest in learning new skill works/trades	2.47	18	2.30	17
Large jobs taking more time	2.31	19	2.33	15
Unpleasant or dangerous task	2.24	21	2.15	20
Learned construction professional	2.25	20	1.90	22
Employed contractors/tradesmen may not achieve one acceptable standard requirement	2.14	22	1.95	21
Enjoy hard physical work	2.03	23	1.75	24
Unemployment	1.86	24	1.84	23

Note: Mean is based on a likert scale of Disagree (1), somehow (2), Agree (3), strongly Agree (4)

Futhermore, owner-occupiers also accepted that high labour charges of skilled workers (2.69), degree of enjoyment and fun involved (2.68), leisure and pleasure (2.59), physical strength (2.62) and law enforcement agencies (2.58) encouraged them to be a

DIY practitioner. But the tenants believed that such factors somehow influence them to be a DIY practitioner. Unemployment and incompetence of contractors and tradesmen among the respondent was not a strong reasons for the practice.

5.3 Determinant Factors Militating Against DIY Maintenance Practice

According to table 3, health and safety issues (2.84), job involving special skills (2.80), lack of information/awareness about DIY maintenance practice (2.80) were major factors that militate against the practice of the system among owner-occupiers. Among the tenants jobs involving special skill (2.69), health and safety issues (2.56), poor emergency preparedness plan in the built-environment (2.56) and stress due to day work (2.55) were major demotivator of the practice of DIY maintenance at home. Lack of availability of DIY tools and building products ranked same i.e (14th) among the two groups of respondents with 2.54 and 2.35 for owner-occupiers and tenant's respectively. Then the non-availability of DIY tools and products had a negative effect on owner-occupiers than the tenants. The two groups of respondent believed that rapid rate of deterioration and damage of building fabrics, high cost of building materials and products, lack of provision of maintenance grants and tools loans and family economic somehow affect the decision of not engaging in DIY practice.

Owner-occupiers also agreed that age (2.59) and time constraint (2.53) were militating factors against the practice. But the tenants considered age (2.34) and time constraint (2.27) as factors that somehow discouraged them from the practice.

Table 3. Determinant factors militating against DIY maintenance
(Source: Field Survey 2010)

Determinant factors militating against DIY maintenance	Owner-occupiers Tenants			
	Mean	Rank	Mean	Rank
Job involving special skills	2.80	2	2.69	1
Health and safety issues involved in DIY maintenance	2.84	1	2.56	2
Lack of technical know-how of installation and removal of building components and elements	2.76	4	2.52	6
Poor emergency preparedness plan in the built environment	2.71	5	2.56	2
Stress due to day work	2.70	6	2.55	4
Large jobs taking more time	2.70	6	2.53	5
Unpleasant or dangerous tasks	2.55	12	2.51	7
Sub-standard materials/products in the market	2.55	12	2.47	9
Lack of knowledge of the life span of building components	2.59	9	2.37	12
Problems of interfaces between building components/elements during installation	2.56	11	2.41	11
Have enough money to engage contractor and skilled labour	2.61	8	2.34	16
Lack of availability of DIY tools	2.54	14	2.35	14
Lack of availability of DIY building products	2.54	14	2.35	14
Involves hard physical work	2.50	17	2.44	10
Age limitation	2.59	9	2.34	16
Lack of builder list and DIY products manufacturers information	2.48	19	2.36	13
Lack of information/awareness about DIY maintenance	2.80	2	2.49	8
Faulty design and construction work	2.47	20	2.33	19
Time constraint	2.53	16	2.27	20
Rapid rate of deterioration and damage of building fabrics	2.41	21	2.34	16
Lack of home maintenance policy/plan	2.50	17	2.24	21
High cost of building materials and products	2.27	22	2.24	21
No provision for maintenance grants and tool loans	2.14	24	2.20	23
Family economic i.e. no capable person to handle DIY	2.16	23	2.10	24
Building maintenance is not necessary	1.46	25	1.43	25

Note: Mean is based on likert scale of Disagree (1), Somehow (2), Agree (3), strongly agree (4).

Also the owner-occupiers agreed that they we not DIY since they can pay a contractor (2.61).The hard physical work involved, unpleasant or dangerous tasks and problem of interfaces were also militating factors against the practice according to the owner-

occupiers. The two groups of respondents agreed that building maintenance is necessary.

5.4 Hypothesis One:

The study further sought to know if there is an association between the factors influencing the practice of do-it-yourself (DIY) maintenance by building owner-occupiers and do-it-yourself (DIY) maintenance practice by the tenants.

H₀: There is no association between the factors influencing the practice of do-it-yourself (DIY) maintenance by building owner-occupiers and the tenants.

Table 4: Spearman rank correlation coefficient of the association between the factors influencing the practice of DIY maintenance,

Variable	r	df	t _{cal}	t _{tab}	decision
Influencing factors	0.96	22	16.23	1.717	Reject H ₀

At **0.05** level of significant and degree of freedom of 22, **t_{cal} = 16.23** and **t_{tab} = 1.717** since **t_{cal} > t_{tab}**, **H₀** is rejected. Therefore, there is an association between the factors influencing the practice of do-it-yourself (DIY) maintenance by building owner-occupiers and the tenants. Also since **r=0.96** it shows a positive association between the variables as shown in table 4. In addition, figure 1.0 indicates the association between the variables graphically.

5.5 Hypothesis Two:

The study further sought to know if there is an agreement between the factors militating against the practice of do-it-yourself (DIY) maintenance by building owner-occupiers and do-it-yourself (DIY) maintenance practice by the tenants.

H₀: There is no agreement between the factors militating against the practice of do-it-yourself (DIY) maintenance by building owner-occupiers and the tenants

Table 5: spearman rank correlation coefficient of the association between the factors militating against the practice of DIY maintenance

Variable	r	df	t _{cal}	t _{tab}	decision
Influencing factors	0.81	30	7.62	1.697	Reject H ₀

According to the table 6, at **0.05** level of significant and degree of freedom of 30, **t_{cal} = 7.62** and **t_{tab} = 1.697**, since **t_{cal} > t_{tab}**, **H₀** is rejected. Therefore, there is an agreement between the factors militating against the practice of do-it-yourself (DIY) maintenance by building owner-occupiers and the tenants. Also since **r=0.81**, it shows a positive agreement between the variables as indicated in figure 2.0.

Figure 1.0: Shows the association between the factors influencing the practice of DIY maintenance in improving housing stock.

Figure 2.0: Shows the association between the factors militating against the practice of DIY maintenance practice in improving housing stock.
(Source: Field Survey, 2010)

6 Discussion of Findings

The study reveals that the factors influencing and militating against the practice among DIY home maintenance practitioner in Lagos State were the same according to table 4 and 5, that shows a positive association between the factors that determine the practice of the system. The effect of gender on the practice shows that more male household heads were involved more than the female counterpart in support of Davidson and Leather (2000). Age limitation somehow militate against the practice (table3). Gronau

1977, believed that age affect DIY productivity. DIY activities increase with unemployment according to Soren Pedersen (2003) but the study was in contrast, unemployment had no influence on practice. Bogdon (1996) find household composition a major determinant of the likelihood of taking on DIY maintenance, with multiple adult households most likely to undertake it. From table 1, most households head were adult within the age of 20 above.

Mintel (2005), stated that quarter of adults claim to enjoy DIY, with 8% identifying DIY as a hobby. Leather et al (1998) attested that people DIY as a choice often for enjoyment, as hobby, a means of self-fulfilment or self expression. Clarke (2000) and Wood (2003), described DIY as the construction and maintenance of self identity and self-esteem. Findings from the study also reveals the same trend of respondents opinion in table 2, habitable environment and acceptable standard, self-satisfaction, degree of enjoyment and fun derived from the practice were influencing factors. Also the issue of leisure time and pleasure at home somehow influence DIY practice.

The issues of competence cannot be overemphasis in DIY maintenance practice. Campbell (2005) stresses on skills, knowledge and judgement in the practice of DIY. Warde (2005) touches on significance of competence in enabling action and reproducing practices. These actually buttress the reasons why the major factors militating against the practice were skills, technical know-how and information.

Enhancing the practice of DIY maintenance in Lagos State, from the oral interview conducted respondents strongly agreed on public enlightenment campaign, educational and vocational training, adoption of modern DIY tools and products technology e.t.c back with an enactment of law by the State government that will mandate housing maintenance. Watson and Shove 2005, identify relatively formal knowledge acquisition such as school CDT (Craft, design and technology) lessons, by referring to DIY manuals, internet forums or being taught by an experience person. Based on the findings, the study recommends that educational and vocational training on DIY maintenance practice should be introduce to schools, craftwork and building end-users, building products should be users friendly and DIY compliances and landlord/tenant covenant should mandate proper building care for building users.

7 Conclusion

Conclusively, the issue of DIY maintenance approach to housing in the study area is subject to factors influencing and militating against it. DIYer's agreed that the major influencing factors for engaging the system were to create a habitable environment, maintain an acceptable standard, to make facilities functional, for self-satisfaction and enjoyment derived from the practice. The factors militating against the system were skills, technicality and information about the system. Both owner-occupiers and tenants were subject to these factors according to the tested hypotheses.

Due to the importance and need for maintenance in residential building. Grassroot participation i.e the direct involvement of building user's in maintenance practice will aid to retain and restore the state and value of housing in Lagos, Nigeria. This can be encourage by the engagement of do-it-yourself maintenance practice by all building user's in their own capacity. Eradicating or reducing the state of disrepair of housing stock experience in the study area today.

Biodiversity and the built environment

Straw Bale Building A Mechanism for the Promotion of Biodiversity Conservation

Robinson J, Goodhew S, McGrath P

Nottingham Trent University

Email: julian.robinson@ntu.ac.uk

Abstract:

In order to stimulate ideas and maximise biodiversity in the built environment the profession requires the correct skills to overcome barriers that prohibit its development. A concern surrounding straw bale building is the development of a robust and effective moisture monitoring system to provide evidence that a building made of straw is healthy. Existing monitoring devices are analysed and reviewed here within, the advantages are extracted and two new methods; a straw probe, and a wood disc are now proposed as suitably proficient. Initial findings are encouraging and demonstrate a stable and comparatively cheap method to assess moisture within the walls of a building. With the development of new monitoring systems it will be possible to provide intensive credible scientific evaluations of straw bale buildings and therefore promote straw bale building as a viable option and enhance its professional status and skillset. This development will enable the growth and integration of key concepts such as the promotion of biodiversity conservation to become a holistic approach rather than a reductionistic method. This will allow a crop, and a building in its construction, use, and eventual demolition to be viewed as a life cycle fully related to the enhancement of surrounding ecosystems linking rural and urban environments through Nature.

Keywords:

biodiversity conservation, built environment, moisture monitoring, straw bale building

1 Introduction

Straw bale building has the potential to become a promoter of biodiversity conservation within the built environment. The European Commission summarises biological diversity or biodiversity as the “variability among living organisms...They form the foundation on which we build our societies.” (European Commission 2011) and matter ethically, emotionally, environmentally and economically. An ecosystem provides emotional and aesthetic experiences, and offers opportunities for recreation. It cleans water, purifies air, maintains soils, regulates the climate, recycles nutrients, and provides food, raw materials, and resources for medicines and other purposes. Nature itself plays a vital role in human health and well-being (Maller et al. 2006).

Conservation is the art of careful management to reveal and share significant and special qualities whilst protecting and enhancing places for the enjoyment and understanding of present and future generations. (National Trust).

The built environment is “the physical world that has been intentionally created through science and technology for the benefit of mankind”. (National Assembly of the Republic Of South Africa 2008), it does not often exist in harmony with nature.

The effect of the built environment on biodiversity is an important consideration and straw bale building offers a mechanism to promote its conservation utilising a natural material. Consisting of the stems and leaf of harvested wheat, barley, oat, rice or rye and bound together to form a bale, straw can be arranged to form a structure.

Stacking straw bales to form a structure does not require skilled labour and therefore there is a perceived lack of professionalism surrounding the process, which brings into question the longevity of buildings. Without due care and attention to detail during construction and the design process there is more potential for moisture penetration and therefore degradation of the bales through bacterial and fungal attack. The problems are in identifying a defective build and in maintaining and developing a highly regarded reputation and skill set for the future of the straw bale building industry. Through careful professional development of this construction method confidence will grow and the promotion of biodiversity can be fully implemented.

Straw is a natural material and has a far greater relationship with Nature than most other building materials providing a direct link to Nature for rural and urban environments. During its lifecycle as a crop it has the potential to be an integral part of an ecosystem. In the form of a construction (as with any type of structure) it can provide shelter for birds and bats, and at the end of its life as a compost material it can provide a habitat for bacteria and fungus which will in turn provide nutrition for an extended ecosystem.

The promotion of this mechanism will encompass different disciplines including the farming community adopting more biodiverse agricultural practices with the addition of field boundaries, buffer strips next to watercourses, and hedgerows as encouraged in schemes such as the Entry Level Stewardship (Natural England).

Planning professionals estimate the social, economic, and environmental impacts of development; this must include ecology “land use, biodiversity and the strategic planning of ecosystem services.”(Jackson 2007). The UK government provides, under Section 40 of the Natural Environment and Rural Communities Act 2006 Section 41 to act as a guide for public bodies to ‘regard’ biodiversity conservation in their normal functions. (Department of the Environment, Food and Rural Affairs 2006)

It is also important that the end users or customers understands or equates to the concepts and decisions behind the building methodologies.

The aim of this paper is to consider the future of straw bale building and how its philosophy can be expanded to encapture biodiversity; its future relies upon the demonstration that it is a valid method of building. To demonstrate this, an accurate and robust technique for professional evaluation of the moisture content must be developed. This will go some way to establishing the building method’s reputation through credible scientific research and the ability to promote it to the wider public, with a focus of educating and inspiring people from all walks of life to invest in a more natural material and consider the greater environmental benefits of these actions.

2 Contextualisation

There can be no doubt that the built environment impacts on nature introducing problem species, water pollution, unsympathetic management, and inappropriate development all threatening wildlife with degradation and/or loss of habitats. (Wilby, Perry 2006)

2.1 Future populations

It is estimated that the world population is set to increase from 6.1 billion in 2000 to 8.9 billion in 2050, to 9.22 billion by 2075 (United Nations 2004). Rodman suggests that a subsequent increase in the amount and concentration of people in urban environment will encourage epidemics, and technical and environmental catastrophes; e.g. flu, nuclear accidents, and chemical spills. (Rodwell 2007)

The population of the UK is projected to rise from 61.4 million in 2008 to 71.6 million by 2033 (Directgov 2009) which will place greater demand on the built environment and even more pressure on the natural environment as the quest for resources and space intensifies, prompting many organizations and governments to review this effect with the purpose of making an informed decision on how to combat it. The Darwin Initiative and Global Youth Biodiversity Organization (GYBO) are some such examples of a move toward addressing this conflict. Straw bale building could also aid the cause.

For wildlife the impacts are already being recognised, the House Martin winters in Africa and returns to the UK to breed, they have become reliant on man made structures in preference to their original choice of cliffs and caves. Evidence suggests that house martin populations have declined by between 25% to 50% due partly to localised weather patterns and wider climate change, loss of nest sites, and reduced insects numbers caused by changes in land use. (Williams 2010)

2.2 Straw Bale Building

With the advent of the first baling machines in the mid-1800's straw could be bundled tightly together and tied to form a bale. Settlers of Nebraska (USA) began stacking them on top of one another to form walls, thus the art of straw bale building was born. King, B et al. (King, Aschheim 2006) and Jones, B (Jones 2002) explain further the history and art of building with straw bales and a number of builds have been featured on Channel 4's Grand Designs programme (Channel 4 2011).

As a construction material, straw bales can provide an excellent insulating medium for both sound and temperature (Lawrence, Heath & Walker 2009) and are an agricultural bi-product that can be locally sourced. Straw is a material with a potential low carbon footprint but using straw as a building material however is not without its drawbacks.

2.3 Drawbacks?

- Insect and animal infestation: They can be deterred by an application of render. (Lawrence, Heath & Walker 2009).
- Fire: The Ecological Building Network have released the following video demonstrating that rendered straw bale walls can have a two hours fire rating: <http://www.ecobuildnetwork.org/resources/downloadable-fire-test-movie>.
- Structural loading: Different building styles and methods of construction complicate this area of study. (Walker 2004)

- Earthquakes: the University of Nevada have published an earthquake simulation demonstrating that it performs well even under extreme shock: http://nees.unr.edu/projects/straw_bale_house.html
- Moisture: The current focus of research is in moisture, specifically at what level it presents a problem, how it is detected and what to do about it?

2.4 Moisture

To prevent the natural cycle that causes straw to decompose the moisture content must be restricted to a maximum of 20% (CMHC 2000). Some other reports and papers vary; King's book evaluates the properties of rice straw with relation to moisture and suggests that only bales with lower than 25% moisture content be used in building structures.

Lawrence et al. recommend a moisture content of less than 15% to prevent decomposition (Lawrence, Heath & Walker 2009) whilst Carfrae et al. state that the received wisdom amongst the straw bale community sets the safe maximum at 25% but emphasises that this be subject to length of time exposed. (Carfrae et al. 2009)

This inability to state an exact point at which moisture begins to cause degradation is partly “dependant on species, variety, climatic conditions, soil type and husbandry. These factors result in significant differences in physical, chemical and biological characteristics.” (Butterworth 1985).

2.5 So why use straw?

Wheat production equated to 54% of the total crop production in 2007 in the UK (Copeland, Turley 2008) partly due to its importance in human nutrition (Evans et al. 1981). Although the root of the plant is often ploughed back into the soil to reapply some nutrients it is not considered good practice to dispose of straw in this way as it provides an ideal breeding ground for specific pests and many diseases of cereals (Grossbard 1979). Consequently there is an estimated 5 to 6 million tonne/annum of straw produced in the UK and yet only 50,000-80,000 tonnes are traded (England Biodiversity Group 2008). Every year 450,000 houses of 150m² could be build with the remaining 4 million tonnes (Watson 2010). The UK National Housing and Planning Advice Unit cautiously predict that the demand for new housing by 2026 will be 223,000 per year average. (NHPAU 2007)

2.6 Straw and biodiversity

A field of wheat can sustain a substantial amount of life, from primary consumers of the wheat to secondary and tertiary organisms. The type of treatments applied to the plant and the way the crop is farmed can have a distinct effect on the local biodiversity. In a publication by the Soil Association evidence suggests lowland organic farming methods support a significantly higher biodiversity than conventional farming systems within the crop and the field margins.(Azeez 2000)

The eradication of weeds from an area around a crop can have a dramatic and negative effect on the local ecosystem causing a reduction in organisms further up the food chain culminating in a decline of top predators. (Boatman Unknown)

In the paper by Siddiqui, M.J.I. et al. organic and conventional wheat field systems were analysed for diversity concluding that agricultural sustainability could be achieved

through scientific manipulation of polyculture and the slow and careful removal of the dependence on agrochemicals. (Siddiqui et al. 2005)

Encouraging practices that are viable both economically and environmentally requires a large amount of skill and knowledge, and requires an understanding from all parties involved in a build, of the benefit analysis involved.

1.1 Justification

Utilising a natural, unestablished material in a construction method allows the promotion of biodiversity conservation. As the element of professionalism develops so to can its skill sets, standards, and credentials, requiring an expansion of the view relating to a product, its origins, use, and eventual deterioration integrated with a concern for the ecosystem it will affect. Timothy Morton has investigated the idea that

Modern Society has damaged the idea of Nature itself by viewing it as an ‘object’ surmising that it should instead be perceived as interconnected with everything. (Morton 2011)

Promoting straw bale building with biodiversity conservation as an integral interconnected part of its system will require the continued professionalism of the construction method and therefore greater research and evidence of the materials viability as a construction medium. Proving that a building is healthy and free from moisture damage is one of the major concerns and will require the adoption of a robust, accurate, and appropriate moisture monitoring system capable of signalling potential future problems and plotting past histories.

Current monitoring methods are analysed and reviewed in the following section the benefits of each have inspired the development of two other methods which will also be discussed.

3 Research Methodology

3.1 Monitoring Methods

Straw bale walls must be monitored and must be able to provide historical records of the moisture levels in order that a critical evaluation of the method of construction may be addressed. The following methods can be undertaken to assess this:

3.1.1 Oven Drying

Samples of materials are weighed, placed into an oven at 105°C and then re-weighed, once the weight stabilises the dry weight has been found. Using one of the following formulas will give an accurate moisture content reading:

$$MC_{(wet)} = \frac{100}{1} \times \frac{W_w - W_d}{W_w} \qquad MC_{(dry)} = \frac{100}{1} \times \frac{W_w - W_d}{W_d}$$

Where W_w is mass of a wet specimen and W_d is the mass of the dry specimen. It is important to note in which result the data is being presented.

This method is highly invasive and involves material extraction and is therefore not a suitable type to be used for regular monitoring.

3.1.2 Electronic Relative Humidity and Temperature Sensors

Placed within a bale and linked to a data logger these sensors can provide a detailed picture of the conditions within the bale. Straube and Schumacher installed some into a Californian winery but did not convert the data from relative humidity into an equivalent moisture content reading. (Straube, Schumacher 2003)

In the paper by Lawrence (Lawrence, Heath & Walker 2009) a formula was devised that could extrapolate the moisture content from the relative humidity:

$$C = \frac{C_s}{1 + n \left(\frac{K_m}{\phi} - 1 \right)^{\frac{i}{3}}}$$

ϕ = percentage relative humidity	
C = Moisture Content	
$K_m = 0.9773$	$i = 1.6$
$n = 44$	$C_s = 4 \quad 0\%$

3.1.3 Existing Bespoke sensors

Protiometer produce the 'Balemaster' primarily for use in the agricultural industry, it is a hand-held device suitable for gauging the moisture content of a straw bale. It's accuracy is questionable as results vary according to the compaction of the bale and it must be used in conjunction with a temperature adjustment; they are expensive, invasive (a metal rod is inserted into the straw), and would not be suitable as a long term monitoring system but do provide a the ability to do a quick background check.

Protiometer also produce the 'Timbermaster' for checking the moisture content of timber. This may also be used in conjunction with the Balemaster's probe but it is important to note that the Balemaster gives a reading in wet percentage and the Timbermaster in dry percentage terms.

3.1.4 Timber probes

There are various versions of the timber probe:

Figure 5. An Example of a Timber Probe & in Exploded View

Timber is used due to its close resemblance in reflecting the moisture content of straw and this design of probe (Figure 5) has an accuracy of $\pm 1\%$ moisture content (Goodhew, Griffiths & Woolley 2004). The probe is pushed into a bale and is allowed to equilibrate with the straw, readings are then taking with a hand-held wood moisture meter via contact with the metal rods providing a conductivity reading that is converted to a moisture reading.

The probes are cheap and easy to produce but require calibration and have been found to suffer from contact issues giving a lower than expected reading. The wood probe can also work free of the body as it expands and contracts with temperature and moisture. These observations have been recorded but are beyond the scope of this paper.

3.1.5 Straw Probe

A straw probe has been trialled with promising initial results. It consists of a measured amount of dry straw being compressed into a non hygroscopic perforated plastic cylinder and inserted into the straw wall as with the timber probe. A conductivity reading from a Timbermaster is then obtained by insertion of two metal rods into the straw.

There is no material assumption to be made as in the case of wood; the compaction is already established and will therefore not influence the results; and it can be withdrawn from the wall and weighed to verify the amount of moisture present. This provides an accurate way of monitoring a wall, but requires weighing scales with ability to read to two decimal places or more. It may not be suitable for intensive long-term studies and is invasive but requires very little calibration prior to use.

3.1.6 Wood disc

Common Oak discs are cut to 3 mm thick across the grain with a diameter of 15 mm. They react quickly to changes of relative humidity due to their reduced thickness and placed directly into a bale will expand in the presence of moisture.

Initial laboratory data shown in Figure 6 illustrates the initial findings of two wood disc's. Expansion relates to the moisture content obtained at differing relative humidities in an environmental chamber set at 22°C.

Figure 6. Graph of wood expansion over moisture content at 22°C

Figure 6 shows a close relationship between moisture content and diameter of the disc measured with a digital scale rule. This initial study requires further investigation, relating to adsorption and desorption with regard to temperature and adaptation to a robust monitoring system.

It is proposed that the wooden discs could be fitted with temperature compensating strain gauges to measure expansion with relation to moisture content of the straw.

Costing far less than relative humidity sensors they could still be connected to a data logger to record the moisture content, the disadvantages however may be that they require lengthy calibration tests and their fragility would be a concern.

1.2 The rig

To test these monitoring methods an outdoor test rig was constructed towards the end of 2010 and monitoring has been setup to record interstitial, internal, and external environments. The rig comprises of walls 225 mm thick and stands two meters tall with a roof footprint of 3000 by 3200 mm accommodating an overhang of 500 mm. The bales are raised 250 mm from ground level on rammed earth car tyres to prevent splash back of rainwater. There are 108 monitoring points within the rig walls which provides a wealth of information; this paper is concerned with only one of those points 'B5.7' as it had the highest overall moisture content prior to construction.

The Rig is not as it stands complete, it has been rendered with two applications of lime render externally to a depth of 20 mm; internally it has had one coat of lime and all 108 monitoring points remain open to the air due mainly to the nature of the experimentation being conducted. The internal environment is influenced directly by the external as there are major air leakage paths yet to be secured. It has no heat source and no roof or floor insulation. The completion of the rig is due to take place after this wave of experiments has ended.

1.3 Data collection

Point 'B5.7' in the rig stands 300mm above ground level, is monitored at a depth of 112 mm. Adopted monitoring techniques include a Maxim iButton sensor, a straw probe, a wood disc, and a Protimeter Timbermaster with Balemaster Probe and temperature probe attachment. It is worth noting at this point that all measurements in this paper will be presented in wet percentage terms.

A hole was drilled into the wall of the rig, the wood disc and iButton were located at the end and the straw probe was then inserted to plug the hole, measurements were taken once a week.

During measurements the straw probe is extracted and weighed in its entirety and the temperature compensated moisture content confirmed with a Timbermaster meter held across the metal rods. The diameter along the grain of the wood disc is then measured with a digital scale rule and the Timbermaster meter with temperature compensation is used to verify the moisture content of the wood. The moisture content of the straw in the wall is then checked with the Timbermaster, and Balemaster probe and temperature sensor attached. Finally the iButton data is downloaded.

Utilising these methods will help to verify the advantages and disadvantages of each method and produce results that can be reviewed and analysed.

4 Findings and Discussion

Figure 7 illustrates the findings from the rig study, the wood disc and iButton sensor have been monitored since the 27th of April 2011, the straw probe since the 5th April and

the Timbermaster with bale master probe attached has monitored the rig from the beginning of the construction.

Figure 7. Moisture Content Comparisons

The ‘weight converted to MC’ (Moisture Content) refers directly to the mass of the straw probe converted using the formula laid out in section 3.1.1 with a negative and positive error obtained from the restrictions of the equipment used.

The ‘Straw Probe: Timbermaster conductivity’ shows a similar trend to the converted weight results but field observations have shown that results can be influenced by applying different pressures to the rods and by poor contact with the straw. The same conclusion can be drawn from the ‘Timbermaster and Balemaster probe’ at around 13.5% moisture there may be a lack of contact between the straw and the probe as it drops off from a steady decline that reflects the straw probe weight conversion data. The contact issues will not be investigated further in this paper.

The wood disc shows that the bale is drying out at a steady rate, it follows within the error boundaries of the ‘weight conversion’ method.

The relative humidity obtained from the iButton sensor converted with Lawrence’s formula confirms that the moisture content is dropping and that it is similar to the results found in the error band of the mass of the straw and of the wood disc.

4.1.1 Rig study analysis

The benefits of the iButton together with the formula and the amount of data that can be collected would prove a tantalising option for a long-term study, but the overall cost and complication of maintaining it over the lifetime of a building may prove inhibitive.

The Balemaster probe has its limitations as is demonstrated by this example as contact is lost a lower reading is obtained reducing confidence in the method. It also requires a lot of effort to take multiple results and is not suitable for long-term studies.

A straw probe offers a very cheap way of manually taking moisture measurements through mass conversion, but conductivity cannot be relied upon as the connection between straw and metal rods cannot be verified and accuracy suffers. Mass conversion may not be a solution to a long term monitoring system over the entirety of a building but could provide a risk assessment tool for a few sample points without jeopardising efficiency of the building.

The expansion of the wood disc may hold a very cheap solution to monitoring at multiple points within a building. With the addition of a strain gauge it should be possible to record data via a network avoiding the sacrifice of an expensive relative humidity sensor every seven years.

5 Conclusion and Further Research

Human populations are set to increase putting greater pressure on the natural environment. Straw bale building may provide a way to alleviate the pressure slightly, utilising a locally produced, abundant, and natural by-product that can be grown to benefit a local ecosystem. Producing an organically farmed crop or employing methods such as field boundaries can help provide extra habitat and prevent pollution of watercourses and therefore encourage an ecosystem.

Straw bale building may be able to spearhead Biodiversity Conservation in the built environment by instilling the notion of Nature as a holistic intertwined and interconnected part of the build over the total life cycle of the material. However to make this possible the method will have to be proved viable. This will in turn requires a skill set to be developed amongst many professions including agricultural, planning and surveying, but above all one capable of proving the health of a build. Presently the lack of credible scientific research is restraining straw bale building from becoming more widely accepted.

The relationship of straw and moisture is of most concern, and in developing a monitoring method capable of demonstrating the history and potential risks in a build will help verify this method of construction. In conclusion, the straw probe and wood disc show encouraging initial results however the need for further study in both methods are required. Further research will be laboratory based to prove performance and reliability and will subject the two new methods to rigorous testing including environmental simulations and cycles of temperature and moisture.

Building procurement

Operating the renewed school estate – an empirical insight into cost and PFI

Abstract:

The use of the Private Finance Initiative (PFI) as a procurement method for capital schools projects over the past decade has been considerable, and a controversial issue. The relevance of procurement method on the operational performance of projects and facilities is an area cited as needing more research by amongst others the National Audit Office. Recently, the relative benefits of rebuilding versus refurbishment have also become an issue, especially in the context of cancellation of the Building Schools for the Future programme, and the James Review of how to get better value from likely decreasing total capital expenditure on schools. In attempting to fill this knowledge vacuum, this study presents comparative samples of normalised expenditures post-renewal on facility services costs in renewed English comprehensive secondary schools. Data is presented in elapsed time relative to year of school renewal, sampled to produce early facility life cost profiles up to a maximum of 9 elapsed years by both procurement method (PFI and Non-PFI), and type of capital works (refurbishment and new / rebuild). The results include that total facility services costs in PFI schools are higher (though not significantly) in six of the nine elapsed years. Total facility services costs are broadly similar over the nine elapsed years following renewal in rebuilt and refurbished schools. The influence of procurement method on expenditure on certain facility services, coupled with high correlations between procurement method and type of capital works, prevents clear conclusions on the independent impact of type of capital works on operational expenditure. As expected, higher expenditures on building maintenance and improvement are witnessed in PFI samples in certain years, in line with life cycle financial modelling principles.

Keywords:

operational cost, PFI, renewal, schools, whole life cost.

1 Introduction

This paper is an empirical study of the on-going facility related operational expenditures of renewed secondary comprehensive schools within England. The analysis seeks to benchmark objectively the operational expenditures of such schools according to:

the procurement route that led to the school's renewal, i.e. via the Private Finance Initiative (PFI) route or not;

the form of renewal undergone, including ‘new build’, ‘re-build’, ‘refurbishment’, ‘partial refurbishment’¹.

The cancellation of Building Schools for the Future (BSF) capital investment programme leaves the issue of a deteriorating school estate unresolved. Lack of national school condition data² means we have no objective data with which to measure either:

change in the overall condition of the estate, on average or as a distribution;

or, specifically, to measure condition in the renewed schools examined here

‘Performance’ of renewed schools can in principle cover everything from educational outcomes to quality of current FM services and asset condition. This paper only looks at FM cost, but is an output from a research project looking at both cost and performance.

The ultimate funding of state provided comprehensive education is always by the taxpayer. However, over the past decade, the use of the PFI to finance upfront investment in schools has been considerable. According to the latest HM Treasury PFI signed project list of March 2011 (HM Treasury, 2011), the Department for Education (DfE) has 162 PFI projects (134 in operation, 28 in construction). The estimated capital value of these 162 projects is £7.76bn. The vast majority of these projects are in fact schools projects, but will include primary as well as secondary schools. In part due to the high transaction cost of arranging PFI projects, and the relatively low capital value of a single school, many PFI projects provide for the construction and maintenance of numerous separate schools within one bundled contract.

It is evident that a considerable amount of the recently renewed school estate is under the regime of PFI construction and operation. This paper seeks to benchmark the operational service expenditures of these schools with comparable recently renewed Non-PFI schools to shed light on relative cost attributable to procurement method.

The School Building Surveys (SBS) of 2007 and 2009 reveal fewer than 15% of comprehensive secondary schools have undergone capital works greater than 50% refurbishment during the period 1992 – 2008. There remains a vast estate in need of investment to reduce a considerable yet uncertain backlog maintenance.

1.1 Aims and objective of this research

The aim of this research is to contribute to a more solid evidence base for the on-going debate concerning the cost and performance of privately financed public infrastructure. The ability to compare the operational cost and performance of social and economic infrastructure by the procurement method applied is an area cited by the National Audit Office (NAO) as requiring work:

“We have yet to come across truly robust and systematic evaluation of the use of private finance built into PPPs at either a project or programme level. The systems are not in place to collect comparable data from similar projects using different procurement routes. Unless such systems are established, together with robust evaluation of the

¹ The form of renewal is as given in the School Building Surveys of 2007 and 2009.

² On this lack, refer to the James Review discussed later.

overall whole-life costs of alternative forms of procurement, Government cannot satisfy itself that private finance represents the best VFM option.”

(Private Finance Projects – A Paper for the Lords Economic Affairs Committee, National Audit Office, 2009b, page 8.)

We sought to help remedy this through sourcing data that is both objective and appropriately comparable. It is expected the audiences that might benefit from this research include private contractors seeking to benchmark their contract performance, as well as public policy makers considering the future of PFI as a procurement method. Some findings of this research were included in evidence submitted by the authors to the Treasury Committee’s 2011 inquiry on the Private Finance Initiative.

2 Theoretical framework and recent insight

The theoretical framework is in part based on the notion of incomplete contracts and private information (Hart et al. 1997; Hart, 2003). Under a PFI contract, specified standards of operational performance must be achieved for the Special Purpose Vehicle (SPV) providing the service to avoid financial penalties. A specified standard of output implies a certain level of expenditure on inputs. It is proposed that this expenditure can take one of three forms, the first being a form of capital expenditure (CAPEX), the later two being subsets of operational expenditure (OPEX):

Upfront CAPEX – leads to a better built or higher specification asset

Annual maintenance – frequent observation and non-capital upkeep expenditure

Life cycle replacement – infrequent renewal of elements of the asset

It has been proposed that combining the design, build and operation (DBO) of a facility into one contract, as in PFI, promotes the optimisation of a whole life cost (WLC) approach, potentially resulting in lower operational expenditures (Hart *et al.*, 1997; Rintala, 2004). That is, there is an option of substitution between the three expenditures above with, in theory, an associated optimum lowest level of total expenditure (in present value terms) able to provide the contracted standards. This optimisation can be considered as the internalisation of a positive externality (Bennett and Iossa, 2006), the externality being the potential for WLC savings when there are separate contracts for D, B and O. This stands whether the investment in lower WLC is verifiable or not, and, as the incentive for this is internalised within the Special Purpose Vehicle (SPV) delivering the project, no bargaining with the public client for such investment is required.

In providing the SPV with a certain enough context in which to realise minimised WLC throughout a 25-year contract, there is a trade off in the flexibility of provision (HM Treasury, 2008; NAO, 2008).

Some question the ability of PFI to deliver efficiency gains in sectors where the quality of the infrastructure can not feasibly significantly reduce operational cost, as it can in transport and water (Iossa & Martimort, 2008).

Furthermore, it is not just the bundling of the contract that is relevant, but the ownership of the asset. This matters especially when investment cannot be verified (Hart et al.,

1997). Placing the asset's ownership within the SPV further incentivises optimal WLC investment to ensure the asset value (in terms of meeting contractual standards and the resulting revenue stream) is maintained.

In theoretical terms, the public sector client cannot observe the investment of effort expended by the SPV, which is therefore said to have private information. There are two types of investment a SPV can make, as discussed by Hart et al. (1997). These include effort spent on efficiency enhancing innovations as well as effort spent on ways to cut cost through shading quality. It is acknowledged that the freedom to innovate and realise WLC has a downside. In this regard, it is anticipated that a well enough specified contract would hinder the ability to shade on quality of operational performance.

To use this theoretical framework, we distinguish 'contractable build quality' from 'design quality' (Ive and Chang, 2007). The former is contractable because it impacts on measurable operational performance or asset durability, and these measures can in turn be linked to payment under the contract.

Given the PFI payment mechanism, we hypothesise that:

SPVs will trade-off capital expenditures on design quality for those on contractable build quality, resulting in higher levels of the latter (than in Non-PFI schools) per unit of CAPEX. This will tend to reduce required OPEX on maintenance and replacement.

The relatively high discount rate SPVs will use in investment decisions, taken together with their ability to commit to levels of maintenance and replacement expenditure, will lead them to spend more on operation relative to CAPEX.

Greater total budgets available for PFI projects than for Non-PFI would result in clients specifying higher standards of operational performance. This would induce SPVs to spend more on OPEX.

Whether OPEX will be higher or lower in PFI than in Non-PFI schools will therefore depend on: (i) their relative CAPEX budgets, and (ii) the relative strength of effect (A) versus (B) and (C).

The relevance of this theoretical framework in this study, driven by the principles of WLC, is limited by the completeness, scope and maturity of available data. We have not been able to control for CAPEX or asset condition of operational facility as yet.

2.1 Recent insight

Little work has been done that compares objective measures of operational cost and performance across methods of procurement. The NAO has made extensive studies of PFI procurement during the construction phase (NAO, 2009a; NAO, 2003), which find that PFI tends to perform better in terms of delivery time and being on budget. There has been one NAO study of the performance and management of PFI hospital contracts. This study found 'the cost and performance of PFI hotel services are similar to those in Non-PFI hospitals' (NAO, 2010, pg. 6).

A similar study to the present one, using central datasets, concerning the provision of soft FM cleaning and catering services found no significant difference in cost between new PFI and new Non-PFI hospitals (Ive et al., 2010). Of the 4 years observed, there

were however instances of statistically significant higher performance levels in terms of higher patient environment ratings, NHS cleanliness scores and food ratings. The data on aspects of hard FM was not of sufficient quality to draw conclusive insight.

The James Review of Education Capital (James, 2011) notes the potential for standard designs and specifications in reducing WLC, through common material specification and lower energy use. The review does not contain similar discussion of the potential for integrated and incentivised contracts. Perhaps an indication the government may not be planning to continue to advocate use of PFI for schools projects.

3 Research method

The aims and objectives of this research were achieved by accessing an official data source¹ of commonly specified public expenditures for all schools. Other reliable public data sources² were then used to develop the elapsed time profile from renewal, and to identify and extract comparable samples of PFI and Non-PFI schools.

3.1 Sampling schools

The sampling and analysis was performed during the summer of 2010 with the most recent available data as it was then. The core sample of renewed schools was created through the following process:

A complete list of over 65,000 educational establishments in England and Wales was obtained from the DfE³. The number of secondary schools within the dataset was 4,225. The dataset was filtered by admission type to include only comprehensives. That left 3,188 schools⁴.

We then cross-matched the 3,188 schools with the SBSs of 2007 and 2009⁵. This identified which schools had received significant capital works amounting to ‘renewal’ between financial years 1992/93 and 2007/08. This included some 403 schools.

A very small number of schools had inconsistent data between the SBS of 2007 and 2009. The data was verified from external sources such as school websites and most such schools were retained in the core sample:

Five schools were removed from the sample as SBS of 2007 and 2009 contained conflicting information;

Two schools which appeared to have been renewed twice were removed from the sample;

One anomalous school was found to be an Academy and was removed.

¹ Consistent Financial Reporting dataset maintained by the Department for Education.

² SBSs 2007 & 2009 and the Edubase.gov educational establishment datasets.

³ Refer to www.edubase.gov.uk

⁴ Other admissions types excluded included ‘selective’, ‘modern’ and ‘N/A’. This step also removed Academies as well as Welsh establishments from the sample, as they did not have sufficient admission type data.

⁵ Survey undertaken by DfE, completed and by local authorities and provided to us by Partnerships for Schools.

The remaining 395 schools formed the core sample. 133 were identified as being PFI schools according to a field within the initial Edubase.gov dataset of educational establishments. The remaining 262 are considered Non-PFI.

9 samples were made, one for each elapsed year from each school's renewal.

3.2 Expenditure variables

These comparative samples were then used to retrieve the associated expenditure data for each school in accordance with the process below:

The Consistent Financial Reporting (CFR) dataset for financial years 2002/03 to 2008/09 was obtained from the DfE. There is thus a maximum of seven years cost data potentially available for a specific school, if it was renewed before 2002/03; reducing to a minimum of one year if it was renewed in 2007/08.

From the range of available expenditure lines, an operational cost basket was created. The basket is not exhaustive of all services provided within a school, but we believe it includes the core soft and hard FM¹ services typically included within the scope of a school PFI contract. The components of the basket, and corresponding CFR reference for clarity, include²:

Building maintenance (E 12);

Grounds maintenance (E13);

Cleaning and caretaking (E14);

Premises staff - in-house caretakers and other similar staff (E04);

Bought in professional services - inc. PFI management fee (E28);

Catering supplies - including contracted catering services (E25);

Catering staff - capturing in-house catering staff (E06);

ICT learning resources (E20).

Expenditures were converted to constant April 2010 prices using RPIX data from the Office of National Statistics. The expenditures for each school were divided by the school's pupil capacity³ for normalisation.

Data for each school were rearranged into elapsed time from that school's renewal using the year of capital works from the SBS as a point of reference.

¹ Hard FM is typically understood to include the management and maintenance of the core fabric of the building. Soft FM services are those pertaining to the management and provision of services provided within the building, e.g. cleaning and catering.

² Detailed descriptions of what each expenditure line includes can be found on the School Financial Benchmarking website: <https://sfb.teachernet.gov.uk/Assets/metrichelp.htm#I01>

³ Provided in the initial Edubase.gov dataset of educational establishments in England and Wales.

The cost data were sampled separately for each of the nine elapsed years after opening of a renewed school facility. A school was only included in the analysis if it had returns for all eight of the operational cost expenditure lines identified above. This was an attempt to minimise the possibility of bad reporting between expenditure lines and cleanse the sample of inaccurate observations.

The final combined actual sample sizes vary from 73 in Year 9 to 203 in year 2.

3.3 Procurement samples – PFI versus Non-PFI renewed schools

The core sample of 395 schools was divided into 133 PFI and 262 Non-PFI schools with reference to a field from the original list of all educational establishments, which indicated if a facility was under a PFI arrangement.

Works type samples – Rebuilt versus refurbished schools

To produce comparative samples for type of capital works, the core sample of 395 schools was divided into 193 rebuilt and 202 refurbished schools. Rebuilt refers to facilities listed in SBS's as either 'new build' or 're-build', and refurbished refers to schools listed as either '80% - 100% refurbishment' or '50% - 80% refurbishment'.

3.4 On statistical testing

Independent sample two-tailed t-tests at 95 percent confidence were used for annual comparisons of total basket expenditure. When interpreting the results, if Levene's test for equality of variance found significance, the *equal variance not assumed* p-value was used. If there is no correlation between the consistency of data reporting from the school and levels of expenditure, then the samples can be considered random samples and applicable to inferential statistical analysis. As we come to understand the data more, we will develop more descriptive statistical techniques.

3.5 Comment on accounting of expenditure

Looking at the definitions of the expenditure lines within the CFR data, the soft and hard FM expenditure lines for PFI schools refer to contract payments. The amounts allocated here will represent the amount paid by the public authority for the associated service as part of the larger Unitary Charge Payment (UCP) for the complete contract.

4 Findings and Discussion

The main findings from the analysis include:

Average total expenditures on the basket of FM related services are higher for PFI school samples in six of the nine elapsed years observed. Non-PFI expenditures are higher in three years. None of the differences of means are statistically significant¹.

As expected, we observe higher levels of *Building maintenance (E12)* expenditures in PFI schools from year 5 onwards, in line with planned life cycle expenditures.

¹ A significant result with assumed equal variance in year 7 is rejected because the Levene's test for equality of variance result is strongly significant.

The *Bought in professional services (E28)* expenditure line is consistently higher in PFI schools. This is as expected as this includes the PFI management fee. There is a considerable increase here going into year 7 of operation. We propose that this is the costing of the contractually obligatory benchmarking and market testing exercises being passed on to the public sector through the PFI management fee.

The level of variance differs significantly between samples. Further work is needed to apportion and explain much of this.

4.3 Discussion

It should be noted that there is considerable correlation between a school being rebuilt and a school being procured through PFI. Around 80% of the rebuilt sample, but approximately 33% of the total sample, comprises of PFI facilities. This provides further insight into the previous findings from procurement cost profiling. It is therefore reasonable to assume that the sample of PFI facilities may have incurred higher up front capital cost, not only because of the incentivisation for lower whole life cost encouraging high specification build, but merely because within these samples, PFI facilities comprise of more new builds and rebuilds, and less refurbishments.

The cancellation of the BSF programme along with notably minimal referencing to the terms ‘finance’ or ‘PFI’ within the James Review, suggests the future scope of PFI capital investment in the school building stock is limited. The current financial structures imposed by the UK government have clearly signalled the cessation of major renewal programmes for social infrastructure assets such as schools. Along with a

political desire to encourage more local decision-making, this financial challenge suggests schools will see smaller and more specific alterations and improvements.

5 Conclusion and Further Research

We believe this is the first study of its kind for the UK. It uses officially collected data on cost and operation of a large portion of the school estate, to inform objectively the debate concerning the relative costs of alternative procurement methods. Using the best publicly accessible data, it has been shown that no years of operation witness statistically significant differences in average total FM basket expenditure between PFI and Non-PFI samples.

Furthermore:

In contrast to the near flat Hard FM expenditure observed in Non-PFI facilities over the first 9 years of operation, PFI facility operators are observed to sustain higher hard FM expenditure from years 5 to 9;

There is significant increase in the *Bought in professional services* expenditure line in PFI facilities from year 6 to 7. We propose that this is explained as the result of PFI operators passing on the cost of benchmarking and market testing activities within the PPP management fee.

In conducting this research, significant time was spent attempting to find data on the physical condition of the built infrastructure. Neither the SBS of 2007 or 2009 asked that an objective metric indicating the condition of the building be provided. Ofsted reports do not provide data on the condition of the physical building, though they do provide assessments of the 'learning environment'. We considered this as an inappropriate proxy for asset condition.

Recommendation 8 of the James review reads:

“That the Department: gathers all local condition data that currently exists, and implements a central condition database to manage this information; Carries out independent building condition surveys on a rolling 20% sample of the estate each year to provide a credible picture of investment needs, repeating this to develop a full picture of the estate’s condition in five years and thereafter.”

(James Review of Education Capital, The Department of Education, April 2011, pg. 50)

The authors wholeheartedly support the establishment of common indicators of asset condition on the principle of ‘what gets measured, gets managed’. Subject to this recommendation being enacted, we propose to revisit this analysis in future years. We are concerned that in an era of austerity and cost cutting, the collection and collation of the data necessary for such analysis will be reduced or even stopped. We urge policy makers to resist such temptations.

We have yet to develop a robust capability to control for capital expenditure. Some data is accessible but further work and consideration is required to establish a method.

Further planned research to build on this work includes:

Development of a parsimonious regression model to estimate significance and size of variable co-efficients in determining soft and hard FM expenditure

Development of a method to incorporate the relevance of initial capital expenditure

Identification of an indicator to control for school building condition

Incorporation of actual numbers of pupils on roll each year, as opposed to pupil capacity, to better normalise the figures

Testing additional variables as available to improve accuracy of comparisons.

6 Acknowledgements

This paper is a result of a project delivered under the Knowledge Transfer Partnership programme, and our thanks go to the Technology Strategy Board for their funding and administration of this innovation project.

The authors extend their thanks to KPMG International for providing match funding for the project, as well as to Dr. Kai Rintala of KPMG for his expert supervision in developing the method and analysis techniques. Their continued collaboration in developing benchmarks of the operational cost and performance of publicly and privately financed infrastructure is gratefully acknowledged.

Finally, the DfE are also thanked for granting access to the expenditure datasets, while Partnership for Schools are additionally acknowledged as assisting through their provision of the School Building Survey's of 2007 and 2009.

Abstract:

A theoretical framework to understand the adversarial relationship between stakeholders in Malaysian construction industry is proposed. It applies the non-cooperative Game Theory (GT) and Transaction Cost Economic Theory (TCE) to traditional procurement. Both theories give insights into the heart of the industry's problem – opportunism in the nature of the relationship among stakeholders especially between client and contractor. There can be a Prisoner's Dilemma situation at the core of the client-contractor relationship, which may be the cause of project inefficiency. This is echoed by the assumption in TCE literature that there are limitations to stakeholder's rationality – bounded rationality, due to the incapacity to process information without error. Such a situation gives rise to opportunism as they need to protect themselves from possible loss. The attitudes of the contracting parties and the cooperative relationships among the project stakeholders are important to alleviate opportunism for successful project delivery. GT that emphasises the importance of future relationship as pre-condition for cooperative behaviours and Relational Contracting (RC) principles found in TCE may serve as a useful strategy towards fostering cooperative relationship and better teamwork within the construction industry. Therefore, a relationship-based procurement arrangement such as strategic partnering will improve project performance. Since the data collection is still ongoing, the discussion and analysis reported were based on the literature review and pilot survey carried out. The findings should provide a strong foundation for further research towards the development of an effective relationship-based procurement model in Malaysia.

Keywords:

adversarial relationship, game theory, Malaysian construction industry, opportunism, transaction cost economics

1 Introduction

Since construction is inherently a project-based activity, in which time, quality and budget are associated with one-time individual project (Dubois and Gadde, 2002), relationships were often built upon on a short-term basis with construction stakeholders attempting to take advantage from one another from an existing project; such

phenomenon often leads to opportunism (Cox and Thompson, 1997; Axelrod, 1984). Conflicts, lack of trust, ineffective communication, uneven bargaining power, and lack of end-user involvement are among the significant shortcomings in a construction project owing to its adversarial relationship (Latham, 1994; Egan, 1998; Chan *et al.*, 2003; Harmon, 2003; Eriksson, 2006).

The Malaysian construction industry has traditionally a lot in common with the construction industry in United Kingdom, Australia and Hong Kong in its industry structure, system, practices and procedures. Therefore, the key problem areas experienced in the Malaysian construction industry are much similar compared to those countries mentioned (CIDB, 2009). The traditional competitive approach to procurement which relied on independent firms bought together by competitive bidding has caused adversarial attitude and fragmentation in the construction industry (CIDB, 2009).

As construction relationships are argued to be adversarial, it is timely to propose a theoretical framework to investigate the nature of such relationship between stakeholders in the Malaysian construction industry. The framework applies non-cooperative Game Theory (GT) and Transaction Cost Economic (TCE) to the widely used traditional procurement in the construction industry. Both theories give insights into the heart of the industry's problem – opportunistic behaviour among stakeholders, especially between clients and contractors.

Understanding the characteristics of this behaviour will enable the researcher to formulate appropriate strategies to alleviate the problem. In this connection, GT that emphasises the importance of future relationship as the precondition of cooperative behaviours and Relational Contracting (RC) principles found in TCE may hold the key towards a more cooperative construction industry. The findings of this study thus provide a strong foundation for further route of the current research on the development of an effective relationship-based procurement model in Malaysia.

2 Literature Review

2.1 Game Theory

Game theory provides some appropriate and useful insights as to what constitutes opportunistic and cooperative behaviours in the construction industry. It is a study of rational behaviour in situations where stakeholders with various objectives participate and where interdependence between outcomes is involved (McMillan, 1992).

Cooperative behaviours describe a series of strategies that generally leads to a win/win conditions. It is characterised by mutual respond. For example, if player A makes a collaborative move, a strategy of cooperative behaviour would require player B to make its next move collaborative in response. On the other hand, opportunistic behaviour describes a series of moves that are adversarial, that the moves are planned to maximise the player's own gain at the other player's expenses, whether or not a collaborative strategy could have yield higher total benefits for both.

The theory is based on three assumptions: individualism, rationality and mutual interdependence. Individualism means that players are individual decision makers with personal and opposite interests. Rationality means that the players will aim to pursue

the best they can for themselves given the resources they have and strategies being played by other players. They can calculate the consequences of their actions and choose the best strategy to maximise profits. Mutual interdependence means that a player's benefits are depended on both his or her own strategy and other player's strategy.

Game theory is predicated on the assumption that the stakeholders are rational. They will aim to do the best they can for themselves given the resources they have and the strategies being played by the other players. Although the interdependencies often generate competition among the players, but games in business such as construction are not purely competitive; the players often have some common interests (Saxby, 2004).

Saxby (2004) further described that playing a game in business is analogous to baking a pie, whose size can increase or decrease as a result of the players' actions. Construction procurement is a particularly complicated "pie" to bake where it involves different stakeholders. The client creates the opportunity and looks to make a profit (usually monetary) and so do the various stakeholders in the project. Challenges lies on whether the players are looking to take advantages at the expenses of everyone else, or they are collaborating to increase the size of the pie.

2.1.1 The Prisoner's Dilemma Game

Game theory and the game - prisoners' dilemma (PD) are useful for analysing client-contractor relationships in construction projects, as they are very similar to such games (Lazar, 2000). In a construction project, there are economic gains at stake, and there can be winners and losers. It involved multiple stakeholders such as clients, consultants, contractors, sub contractors and so on. Different strategies are undertaken by different parties and the outcome usually depends largely on the appropriate choice of strategies and how well each strategy is executed. The PD game is one of the games that fit the situation of a construction project well.

Prisoner's Dilemma is a 2-person nonzero-sum game that can be applied to describe the conflict between individual and collective interests in many different political and economic situations, such as inter-organisational relationships (Zagare, 1984). Strategies available to the players are competitive, collaborative, or a mixture of both. Each player can choose to cooperate or to defect, resulting in one of four pay-offs as below:-

		<u>Player B</u>	
		Cooperate	Defect
<u>Player A</u>	Cooperate	R, R	S, T
	Defect	T, S	P, P

Figure 1. Symbolic pay-off structure of Prisoner's Dilemma (Source: Zagare, 1984)

A PD requires $T > R > P > S$ and $R + R > T + S$. T is temptation to defect, R is reward for mutual cooperation, P is punishment for mutual defection, and S is sucker's pay-off (worst outcome). It is predicted that each player in rational will pursue his own selfish ends. They will choose to defect from cooperation even though they are both better off to cooperate (Romp, 1997). A hypothetical example of PD in the construction industry will help to explain the overall idea.

3.1.1 Hypothetical Example

Two parties, (the client and the contractor), have engage one another in a construction project, both seek to obtain profits from it. After the initial project briefing, both parties are being advised by their independent advisor with the following offer:-

- If you take advantage and the other party does not, you will gain the maximum 30% profits, but the other party will experience a 20% loss.
- If you did not take advantage and the other party does, you will experience 20% loss and the other party will gain the maximum 30% profits.
- If you both of you take advantages on one another, you will both experience a 10% loss.
- If neither of you take advantages, both of you will share the profits.

*take advantage = contractors search for extra work (variation) and clients' rejection of contractors' suggestions regarding alternative solutions.

It is helpful to reformulate the numbers given above into a simple hierarchy of preference as follows:

Preference Rank	Outcome	Label
4 = Best Outcome	30 %profits	"Temptation" (T)
3 = Next Best	15% profits	"Reward" (R)
2 = Next Worst	10% loss	"Punishment" (P)
1 = Worst	20% loss	"Sucker's Payoff" (S)

Axelrod (1984) labels the various pay-offs as "temptations" (T), "rewards" (R), "punishment" (P) and "sucker's pay-off" (S). Assuming the client and contractor are rational, what will be their best response? The choices available to them can be presented in the following pay-off table:

Table 1. Pay-off structure of Prisoner's Dilemma in hypothetical example.

	Contractor		
		Cooperate	Defect
Client	Cooperate	3	1
		3	4
	Defect	4	2
		1	2

The number on the left of each column represents the payoff for client and those on the right for contractors. The “dominant strategy” in this game is to take advantage from one another as it is better in some instances and not worst at any. Due to rational calculations, both players are caught in a loss/loss situation. Each player, in pursuing his own selfish ends, defects from cooperation even though there was a better outcome, if they had been able to cooperate (Romp, 1997). The result of a Prisoner's Dilemma is therefore an “*inefficient equilibrium*”. As a conclusion, the dilemma exists where there is a short term, higher payoff for defection compared to cooperation.

However, if the players have opportunities to cooperate in future projects, cooperative behaviour can emerge. For example, if you are a client who can offer long term, profitable work to a contractor, strategic partnering is then a viable solution. The payoff structures change dependent upon how valuable the future is. Hence, it is no longer rational to defect on the first move. On the other hand, empirical researches have shown that the amount of trust between players will also affect cooperation in PD (Morgan and Hunt, 1994; Lazar, 2000). While trust and future relationship discouraged opportunistic behaviour, the strategy becomes more focused on cooperation than defection. When relationships improved, there are fewer needs for costly monitoring and control, which in turn decrease transaction costs. This will increase the profits of the current and future transaction while strengthening the cooperative spirit of the team.

2.2 Transaction Cost Economics

Another framework that has gained much interest in construction management research is transaction cost economics (TCE). TCE is a theory that indicates strategies to organise different projects (transactions) from an efficiency point of view (Williamson 1996). Efficient governance is achieved by the minimisation of transaction cost, which are those incurred for searching and gathering information on buyer and seller, writing and negotiating contractual agreements and administering their execution.

TCE is based on assumption of bounded rationality and opportunism. Bounded rationality means that there are limitations to the stakeholders' rationality, due to the incapacity to process information without error. Opportunism implies that stakeholders are self-interest seeking, they will deviate from the agreement whenever it suits their purpose and agenda (Williamson, 1985). Even though all stakeholders are not assumed

to be opportunistic, but it is difficult to identify opportunistic stakeholders *ex ante* (Rindfleisch and Heide, 1997).

According to TCE theory, there are three principal transactions characteristic: asset specificity, frequency/duration as well as uncertainty. Asset specificity refers to the dependence created through transaction-specific investments and the switching cost incurred by terminating the relationships and choosing another party. It mainly depends on the level of complexity, uniqueness and adaptability of the assets required for the exchange (Hakansson and Snehota, 1995). Frequency/ durations refer to the times the transaction is repeated. The time horizon may affect the relationship between stakeholders as recurring transaction may be governed within long-term relationships, an expectation of continuity may arise and thus cooperative behaviour may be fostered (Noordewier *et al.*, 1990). Uncertainty may arise due to unanticipated changes in circumstances surrounding the transaction leading to adaption and performance problem. (Noordewier *et al.*, 1990). In short, the greater the transaction uncertainty and asset specificity and the lower the transaction frequency, the higher is the transaction costs.

2.2.1 Governance structure

Construction contracts are seen as ‘governance structure’, that is, as frameworks for conducting transaction (project). Transaction can be governed within three main structures which are market, hierarchy and the intermediate *hybrid* structure, which map into price, authority and trust respectively. Williamson (1985) presents a model for the choice of an optimal governance structure for six different type of transaction, depending on their asset specificity and frequency.

Table 2. Model for the choice of governance structure
(Source: Williamson, 1985)

		Asset specificity		
		Low	Medium	High
Frequency	Occasional	Market Purchasing standard equipment	Trilateral hybrid Purchasing customised equipment	Trilateral hybrid or Hierarchy Constructing a plant
	Recurrent	Market Purchasing standard material	Bilateral hybrid Purchasing customised material	Hierarchy Site-specific transfer of intermediate product

According to the TCE framework, most of the construction projects are governed within the hierarchy structure where the transaction is usually given by the authority (client) to the agents executing them (consultant and contractors) (Larsson, 1993). It goes through

a process of constant coordination and monitoring in order to achieve the required organisational goals. Even though it ensures certain level of stability, however, it decreases mutual participation and effective communication which in turn reduce commitment and motivation from the involved parties (Das and Teng, 2001). In addition to that, the uncertainties about future prospect and contingency factors (economic and weather conditions, availability of resources) and the high asset specificity often lead to opportunistic behaviour.

2.2.2 Relational Contracting

TCE considers that the underlying behaviour of a particular transaction is always expected to be opportunistic and therefore ‘negative’. Nevertheless, this problem can be mitigated by the suitable choice of contractual form (or overall governance structure), which depends on the characteristic of each transaction. Apart from market and hierarchy structure, the third type of governance structure – *hybrid* structure in TCE framework may provide an answer to the industry’s opportunistic behaviour. Williamson (1996) referred to such governance structures as ‘relational contracting’.

Relational contracting is based on the recognition of mutual benefits and win-win situations through cooperative behaviours and trust between the contracting parties. It represents a wide range of cooperative arrangement, such as long term contracts, partnering, alliancing, joint venture as well as better risk sharing mechanism (Blois, 2002) that are governed by trust. The formation of trust within the construction stakeholders can decrease the need for formalisation of contract as well as stringent monitoring procedure, leading to lower transaction cost and facilitate incentives for the party to cooperate. This can be done by lengthening relations through future projects, sharing risks in alliance agreement, or increasing the importance of reputation and co-operative skills in relation to price in traditional procurement. Characteristics of relational contracts and construction contracts adapted from Rowlinson and Cheung (2004a) may give a better idea on relational contracting.

Table 3. Characteristic of relational contracts and construction contracts
(Source: Rowlinson and Cheung, 2004a)

	Relational Contracts	Construction Contracts
Contracting Environment	<ul style="list-style-type: none"> • Cooperative instead of defensive. • Proactive instead of reactive. 	<ul style="list-style-type: none"> • Cooperative, mutual trust is the desired static of contracting
Effectuation	<ul style="list-style-type: none"> • Flexibility and Adjustments provisions to cater for unanticipated contingencies. 	<ul style="list-style-type: none"> • Power to issue variations with associated time and cost adjustments
Dispute Resolution	<ul style="list-style-type: none"> • Relational Dispute Resolution. 	<ul style="list-style-type: none"> • Alternative Dispute Resolution

Many studies have been conducted to look into the possible ways of improving project performance in Malaysia (Al-Tmeemy *et al.*, 2011; Takim and Adnan, 2008; Sambasivan and Yau, 2007; Abdul-Rahman *et al.*, 2006). However, there has yet been any widely published research that has described construction stakeholders’ attitudes and behaviours in relation to project success. Most of them have failed to look into the heart of the industry’s problem – opportunism in the nature of the relationship among stakeholders especially between client and contractor. Even though various dimensions

of project success have been discussed, but the researchers have remained relatively silent on the matters relating to opportunistic behaviour and the lack of trust among construction stakeholders in Malaysia.

Understanding these two important variables will enable the researcher to address the core problem in the industry and to further develop an effective procurement model that promotes the formation of trust and instil greater level of confidence among stakeholders. Without addressing the opportunistic behaviour and the lack of trust at first, other strategies and efforts on project success would be futile.

3 Research Methodology

As the study is at the early stage of the research, it is beyond the scope of this paper to discuss any concrete research methodology. However, potential research methodologies have been reviewed and adapted for this research. As part of the wider on-going research, this study would satisfy the qualitative nature / “interpretivist” philosophical stance of the research, in order to gain a deeper and specific understanding of the construction industry in Malaysia.

Apart from the theoretical framework discussed, semi-structured interviews with clients and contractors in the Malaysia construction industry will be carried out to obtain empirical data concerning especially the bidding process, the contractual relationship and the level of trust between both parties in order to corroborate with the assumptions made in the framework. It shall provide vigorous findings for the further research towards a development of an effective relationship-based procurement in Malaysia.

Samples for the semi-structured interview would adopt a purposive sampling approach. For this study, the samples will be selected based on the size of their company as well as nature of participation in different project type such as residential projects, commercial projects, mixed development and infrastructure work.

4 Findings and Discussion

Table 4. Overall ranking of top fifteen critical success factors contributing to the success of construction projects in Malaysia.

Factors	Mean	Std. Dev.	Ranking	Categories
Financial Capability	4.818	0.386	1	Client
Control of subcontractor works	4.818	0.386	2	Contractor
Competence	4.727	0.445	3	Consultant
Cooperation in solving problems	4.636	0.481	4	Consultant
Competence	4.545	0.656	5	Team Leader
Commitment	4.545	0.498	6	Consultant
Skilful worker	4.545	0.656	7	Contractor
Adequacy of design details & specification	4.545	0.498	8	Contractor
Industry related issues (availability of resources)	4.545	0.498	9	External
Commitment	4.455	0.656	10	Contractor
Communication among project stakeholders	4.455	0.656	11	Consultant
Involvement to monitor the project progress	4.455	0.656	12	Contractor
Effective allocation of man power	4.364	0.481	13	Project
Shared authority and responsibility among clients, consultants and contractors.	4.364	0.643	14	Procurement
Nature	4.364	0.643	15	External

A recent pilot survey was conducted to assess the critical success factors for the construction project in Malaysia. The questionnaire was distributed to three target

groups: private developers, consultants and contractors. The respondents were required to identify, from the list of factors, which they agreed to be critical to the success of construction project in Malaysia.

Based on the findings tabulated in table 4, a total of fifteen top critical success factors were consolidated from the thirty-seven factors being examined. The study recommends that more emphasis should be given on improving the human relationship factors such as competence, commitment and communication in order to ensure the successful implementation of construction project in future.

The findings are in line with the assumption of the theoretical framework proposed in this paper. As demonstrated by GT and TCE approaches, the traditional procurement is seen as an inefficient process as it promotes delayed payment progress, excessive demand and variation as well as unrealistic competitive bidding. This is due to the nature of the procurement procedure which encourages opportunistic behaviour to emerge since decisions were made based on human rationality.

On the other hand, the findings are also coherent with the growing trend in recognising the importance of human relationship factors towards project success (Toor and Ogunlana, 2009; Andersen, 2006; Dainty *et al.*, 2005; Chan, 2004; Walker and Hampson, 2003; Nicolini, 2002). Fellows (2010) emphasised that in order to 'inflict' a paradigm shift in the construction industry, it is crucial for the researcher to recognise the significance of human factors – the soft elements that are 'critical' to the success of the industry alongside with thorough cultural assimilation, understanding and support from top management.

Therefore, in order to improve on project performance, the industry needs to look into strategies that alleviate opportunistic behaviours and promote better working relationship among project stakeholders. This can be achieved through the development of mutual trust within the industry by adopting a relationship-based approach in procurement. Mutual objectives, structured problem resolution mechanism, teamwork initiatives, top management advisory, incentives programme and continuous improvement strategies from relationship-based procurement (Walker and Hampson, 2003) may enhance the mutual level of trust within the industry.

Nevertheless, it should also be noted that based on PD assumption, a change of adversarial attitude alone does not guaranteed the success of the construction project but rather it is the prospect of future projects that is critical to the development of cooperative behaviour in the industry. Hence, the relational contracting principles found in TCE that encourage the formation of long term relationships may serve as a useful strategy towards fostering co-operative relationship and teamwork within the industry (Rowlinson and Cheung, 2004a)

5 Conclusion and Further Research

It is insightful to apply non-cooperative game theory and transaction cost economics to traditional procurement. Both GT and TCE were studied in detail to form a theoretical framework that gives a clearer understanding towards the nature of the opportunistic behaviour among construction stakeholders in Malaysia especially between the clients and contractors.

Based on the current findings, it is made known that the nature of adversarial relationship within the construction industry is originated from the opportunistic behaviour caused by human rationality/ weaknesses. It is evident that the industry itself recognised the existence of adversarial relationship and opportunistic behaviour in the industry's practise, and they are now demanding a change from the current situation.

The prospect of future work played a critical role in escaping from such situation. Industry at large should look at contractual arrangement that can offer a future such as strategic partnering and alliancing. Apart from that, the construction industry development board should encourage and educate the stakeholders on the benefits of cooperative approaches. Government agencies should be the pioneers and projects champions that start to adopt cooperative measure in their project management.

As this is an on-going study, the next stage of the research would be to carry out the interview process for obtaining empirical data for further analysis.

6 Acknowledgement

This paper is part of a larger research project towards the development of an effective relationship-based procurement model in Malaysia. The author would like to thank the Universiti Teknologi Malaysia (UTM) for the funding provided under the Zamalah scholarship scheme without which will be impossible for the author to finish the study.

Abstract:

Housing Associations have a responsibility to provide well maintained and functional properties, therefore, must continually upgrade or build new properties to accommodate tenants. A recent report published by Gibb and Leishman (2011) highlighted that Housing Association grants from the government for new build properties were likely to be drastically cut, with new funding methods, including private sector participation being explored. Value for money achieved by Scottish Housing Associations has remained a constant driver throughout the recession. The challenging economic times have placed significant importance on social housing providers achieving value for money from all construction and maintenance projects. The economic climate may tempt construction clients to revert to lowest price, traditional procurement, as contractors cut margins to survive the business environment. A reversion in procurement method is a divergence away from the advocated use of collaborative partnering arrangements. UK central government has advocated the use of partnering, by public sector or quasi-public sector organisations to achieve best value. There is however, criticism, not only associated with the concept of partnering, but specifically partnering within the public sector. This paper assesses the historical benefits and limitations associated with partnering arrangements and the concept of value for money. Understanding the principals of partnering and value for money enables assessment of the validity associated with Scottish Housing Associations utilising a partnering procurement arrangement when striving to achieve value for money. The findings show that Scottish Housing Associations may achieve value for money, through the implementation of a partnering procurement arrangement, which significantly eases the cuts in spending and optimise the investment of capital for necessary projects.

Keywords:

partnering, procurement, Scottish housing associations, value for money

1 Introduction

The current requirement for Housing Associations (HAs) to achieve value for money (VFM) during the difficult economic climate has never been as crucial. With substantial spending cuts being introduced, Scottish Housing Associations (SHAs) have been

instructed to maximise the level of value achieved. SHAs have embraced the partnering procurement method, however the current economic climate has dictated that construction clients may be tempted to revert to traditional procurement. The low price tenders submitted by contractors attempting to survive the business environment, appear to being capatilised upon by clients to drive down costs. Strongly opposing this strategy, Sir Michael Latham (2008) emphasised that if clients abandon best practice, close down frameworks, stop partnering, and return to lump-sum, single-tender contracts, based solely on lowest price, the industry will go back to its undesirable practices. Within the context of SHAs, the Scottish Housing Regulator (2011) commented that as the quality of the housing stock has improved at a steady pace it was believed that some landlords may have been able to take advantage of falling tender prices during the current climate. Despite this, publications have identified that lowest price tenders do not represent VFM (OGC 2003; OGC 2007). There is therefore a risk that SHAs reverting to lowest price tenders, will not achieve VFM, thus limit the level of investment to develop new properties and maintain existing dwellings.

Partnering has been endorsed through Government publication as an effective procurement method, which should provide cost, time and quality benefits (Latham, 1994; Egan; 1998; OGC, 2003). HAs have been encouraged to use partnering, when possible to achieve positive results. There may be an argument however that the differing characteristics of HA clients could prevent partnering from effectively functioning. There is a requirement to ensure demonstration of competitiveness within public sector and quasi-public sector procurement to protect the taxpayer against anti-competitive behaviour that can result from partnering agreements (Fisher and Green, 2001). Another characteristic is that procedures implemented by the Public Sector can often work against the mutual trust and open relationship, which forms the prerequisite of partnering (Woodrich, 1993). HAs may also be prevented to applying an agreed share of savings with the contractor. The Housing Forum (2000) highlighted that this may be due to individual financial standing orders or the perceived need to have a fiduciary duty to tenants and the taxpayer.

HAs are not-for-profit bodies, who are committed to providing low cost social housing to society, as opposed to private sector organisations that focus on profit. Excess income is re invested into maintenance and development of properties. The differing characteristics may prevent the historical and generic benefits of partnering being achieved, therefore historic limitations of partnering may manifest into SHA projects. The necessity for SHAs to achieve VFM was highlighted by the Housing Minister in the Scottish Parliament, Alex Neil Scottish Government (2010), emphasising that achieving VFM was an essential element to underpin the Scottish Government's future investment programme in housing. The requirement to identify the applicability of the reviewed benefits and limitations of partnering within the context SHAs is necessary when considering that approximately £326m was spent by SHAs in 2009/2010 for planned and reactive maintenance alone and the number of new build properties constructed in 2009-2010 was 8,092 (Scottish Housing Regulator, 2011). The motivation for this paper is to therefore identify the historic benefits and limitations of partnering. The validity of the reviewed benefits and limitations will be tested within the specific context of SHA clients in the near future. Understanding the benefits contributing to VFM or the limitations failing to achieve VFM, will provide much needed clarity to identify if partnering will facilitate the achievement of VFM.

2 Literature Review

2.1 Housing Associations and Partnering

HAs and Cooperatives have functioned in Scotland since the mid-1970s in response to the continual failures of both private and public sectors to deliver high quality, affordable rented housing. Scottish Federation of Housing Associations (2011) highlighted that SHAs have been at the forefront of developing, building and managing high quality homes for the past 35 years. HAs have continually contributed to public housing policy, providing a range of housing solutions at both local and national levels. The importance of SHAs is emphasised through evaluating the proportion of housing they manage. A recently published report from the Scottish Federation of Housing (2011) highlighted that currently, HAs and Co-operatives own and manage approximately 47% of Scotland's affordable social housing stock. The percentage translates into 279,144 dwellings, equating to approximately 11% of all Scottish homes, resulting in an indicative value of SHA assets of approximately £7.6 billion.

The report published by the Scottish Housing Regulator (2011) highlighted that the sector medians for direct maintenance costs in 2009/2010 were £574 per house for planned maintenance, compared with £505 in 2008/2009, and £402 per house for reactive maintenance, compared with £416 in 2008/2009. The Scottish Housing Regulator (2011) further noted that although £192.1m, total planned maintenance across the sector has increased by approximately 3.0% from the 2008/09 level (£186.6m), the per house increase is minimal at 0.88% from 2008/09 when adjusted for inflation. The figures do however highlight that reactive maintenance costs have decreased. This is demonstrated in total across the sector where a drop of around 3.6% took spend in 2009/10 down to £133.9m from £138.9m in 2008/09, and also per unit house where a slightly bigger drop of 5.2% took the spend down to £477 from £503 in 2008/09.

The recent budget proposed by the Scottish Government (2010) reduces the total amount of funding to support provision of new build by HAs. It is now apparent that new build programmes will rely on a greater level of funding from HAs own reserves or borrowing capacity or some combination of both. The Scottish Housing Regulator (2011) emphasised that this has the potential to increase the financial risk attaching to the sector as a whole as well as to individual RSLs, should they continue to build in this necessary method. An essential factor associated with private funding and increase risk allocation is the achievement of VFM for both new build and maintenance by SHAs. Adopting the most effective procurement method to achieve this is now of vital importance to increase the level of VFM attained. Failure to achieve this will only exacerbate the limited funding available.

HAs have been encouraged for some time to utilise partnering agreements as the preferred procurement method for delivering construction and maintenance projects. Partnering was described by the OGC (2003) as the integrated project team working together to improve performance through agreeing mutual objectives, dispute resolution methods and committing to continuous improvement, measuring progress and sharing the gains. SHAs invest significant capital in maintenance, refurbishment and new build projects annually. Loraine and Williams (2000) stated that partnering for HAs is based on a number of key objectives, which include: cutting out waste; increased predictability of out-turn cost and time; reduce the impact of traditional client/contractor procedures, resulting in increased costs; the need to improve the experience of the

user/tenant in terms of communications and quality; the need to secure life-cycle cost benefits; the desire to utilise innovation and technology to maximise resource potential. Identifying the actual benefits or limitations received by SHAs through the utilisation of partnering will uncover the legitimacy of use and endorsement within a SHA context.

2.2 Value for Money (VFM)

VFM is a term utilised not only in construction but all procurement processes, especially within the public or quasi-public sector. The fundamental ethos of VFM can be characterised through three principles, namely: Economy, Efficiency and Effectiveness. Economy encapsulates the price paid for the service, efficiency is the measure of productivity and effectiveness is the measure of impact achieved. The Audit Commission (2005) believed VFM is achieved when there is an optimum balance between the three factors. The Audit Commission however fails to discuss the relationship between the factors on a quantitative basis, suggesting that value assessment should be formed through an overall judgment of quality in relation to cost.

The OGC (2007) advocated that the primary consideration in defining a procurement strategy is the need to obtain overall VFM in the whole life of the service or facility. In agreement and within a HA context, the Chartered Institute of Housing (2007) emphasised that VFM is a fundamental business driver both from within HAs and in terms of regulatory expectations. The potential resurgence in traditional procurement due to the economic climate contradicts the policy identified by the OGC (2007), highlighting that traditional procurement should only be used where it can be clearly demonstrated that this approach will provide better VFM than preferred integrated procurement routes, including partnering. On this basis, construction clients may consider the notion of lowest price tenders as superseding the overall benefits of achieving VFM. HAs must be made aware of the validity of the historic benefits associated with partnering to discover if VFM will be achieved. Should the limitations of partnering be more relevant to HAs, the reversion to traditional for lowest price tenders may actually be beneficial to the HAs during this economic climate.

2.3 Partnering Benefits

The following benefits and limitations in Section 2.4 have been identified through a literature review, applying generally, without specific focus on client group. Understanding the applicability of the theoretical benefits or limitations of partnering to SHAs is important during the economic climate.

2.3.1 Reduced Litigation

Litigation can be a significant issue in many construction projects, but is more prevalent in traditional contracting arrangements. Chan *et al.*, (2003) believed that partnering arrangements greatly reduces issues of disputes, claims or litigations through open communication and improved working relationship. This could be beneficial to SHAs during an economic climate conducive to arising disputes and claims.

2.3.2 Effective Cost Control

Partnering can result in effective cost control, which can result in a reduction of overall project costs. Pheng (1999) highlighted that one of the benefits for both the client and contractor that can be achieved from partnering is the reduction in risk of cost over runs, due to more effective cost control. Should partnering enable more effective cost control,

SHAs could ensure that spending budgets are not exceeded, and continually strive for potential savings through setting mutual objectives between the partners.

2.3.3 Effective Time Control

More effective control of time could significantly facilitate SHAs, as mitigating tenant disruption during maintenance or refurbishment works could increase tenant satisfaction. Black *et al.*, (2000) emphasised that partnering can reduce delay as a result of better schedule performance. There is however a large input of time and resources needed to effectively set up a partnering project. SHAs must consider the resources available and the time needed to implement the partnering arrangement.

2.3.4 Improve Quality

Pheng (1999) identified that partnering arrangements facilitate communication of quality issues and enables earlier recognition of potential problematic issues, through focussing energies on the ultimate mutual goal therefore facilitates the development of quality consciousness. The literature consensus advocates a higher degree of quality available to the client through adopting a partnering arrangement. The nature of HAs providing accommodation for tenants dictates that quality is an important priority, therefore the validity of this perceived benefit must be confirmed for SHAs.

2.3.5 Increased Overall Satisfaction

When considering satisfaction for SHAs, the actual satisfaction of the tenant is vital. The HA must also be satisfied from the outcome of a project, however this is intrinsically related to the satisfaction of their tenants. If this can be achieved by the SHA being closer to the construction process and better informed through utilising partnering, this will contribute to the overall VFM.

2.3.6 Improved Health and Safety Performance

Chan *et al.*, (2003), suggested that partnering organisations taking collective responsibility can reduce the risk of hazardous working conditions and avoids workplace accidents. The substantiation of the belief that health and safety performance will improve through partnering remains elusive. A procurement method should not have any implications on the health and safety performance.

2.3.7 Reduced Administrative Costs

Chan *et al.*, (2003), identified that costs associated with negotiating and administering contracts is lowered as partnering organisations become knowledgeable of the counterpart's legal and litigation concerns. The current economic climate could justify SHAs deciding not to invest these initial resources as funding is reduced. A detailed evaluation should be undertaken by the HA to assess the feasibility of expended resources on this start-up period.

2.3.8 Increased Innovation

Increasing innovation through the high degree of open and trustworthy communication may improve the design and construction phases of a project. Jones and O'Brien (2003) believed that partnering can enable more innovation for products and processes related to delivering greater end user value and enhanced whole life performance. Innovation

could be jeopardised if complacency enters the arrangement through time as partners may become too comfortable and not strive to continually innovate.

2.3.9 Sharing Risks and Resources

A pre-requisite of partnering is sharing risks and resources. Chan *et al.*, (2003) believed that partnering can also produce the tools for both measurement and sharing of gains and risks. This could be more difficult within the public sector as sharing savings made with a private sector organisation, could be perceived by taxpayers as wasteful.

2.3.10 Efficient Problem Solving

Jones and O'Brien (2003) noted the increased collective learning arising from joint problem solving contributing to more effective decision making, more understanding of the process, increased trust and greater commitment. SHAs could work closely with partners to anticipate problems and formulate action plans to address problematic issues.

2.4 Partnering Limitations

2.4.1 Decentralised Decision Making

Decentralised Decision Making could hinder the success of the project. Bennett and Peace (2006) suggested that modern forms of decentralized decision-making can potentially undermine partnering as decisions by one department are contradicted elsewhere. A SHA decision making process could hinder the flow of decision making within the arrangement and therefore oppose the ethos of the partnering arrangement.

2.4.2 Increased Interdependency

Partnering can inadvertently promote a degree of increased dependency, which could negatively affect the quality of output. Cartlidge (2002) highlighted that there is a potential risk of increasing the level of interdependency amongst partnering organisations within strategic relationships, with possible ideas becoming stale due to lack of new players. SHAs and their partners must ensure that interdependency does not manifest into the arrangement, which would negatively affect the outcome.

2.4.3 Early Commitment of Resources

Partnering arrangements normally involve the commitment of resources early, which, may result in not realising rewards for a prolonged and considerable period of time. Jones and O'Brien (2003) noted that a considerable investment in time and resources is required to build closer and more open relationships. An indication of the expendable level of resources should be provided to SHAs for them to assess the feasibility of implementing partnering for specific projects.

2.4.4 High Professional Fees

Cartlidge (2002) suggested that consultants are involved in extra work due to the increase in alternative solutions arising and require consideration. This importantly highlights that SHAs must consider the cost for consultancy fees when assessing the feasibility of implementing a partnering arrangement. An estimate should be incorporated within the assessment of likely resources to be committed to the process.

2.4.5 Increased Complacency

Partnering provides continuity for parties over a period of time. There is a risk that this could lead to complacency within a project. Cartlidge (2002) noted a risk that partners may become complacent and relationships become too familiar and cosy. Human nature dictates that this limitation could easily manifest within a SHA partnering arrangement. This could result in SHAs becoming unfamiliar with the market, and the benefits of downward trends may not be passed on to clients tied into long-term agreements.

2.4.6 Inequitable Distribution of Risk

The allocation of risk should be governed by the partner more able to cope with the risk. Roe and Jenkins (2003) emphasised that risk apportionment should reflect the appropriate level to each partner, encouraging firms to place the necessary commitment into the relationship. If SHAs do not ensure an equitable and sensible distribution of the risks, there is a high probability that the theoretical benefits will not be achieved.

2.4.7 Loss of Confidentiality

The possible loss of confidentiality associated with proprietary information could result in the competitive edge being compromised. Ashworth and Hogg (2007) highlighted that confidentiality could also be compromised in the event of an arising dispute. SHAs would have to ensure clear communication with their partners that sensitive information remains confidential at all times and is not disclosed within the public domain.

2.4.8 Lack of Competition

European Procurement Law requires a degree of competition to ensure competitive prices and the opportunity for parties to tender. For public sector projects, a partnering arrangement could place non-partnered contractors at a disadvantage during tendering as Olsen and Espling (2004) suggested that the partnering contractor could possess restricted information on the public sector body, thus reduce competitiveness. SHAs must ensure a rigorous competitive tendering process is undertaken at the beginning of a long term partnering arrangement, adhering to current procurement legislation.

2.4.9 Corruption

One of the perceived limitations of partnering is the potential for corruption to enter through time. Hibberd and Newman (1999) noted the increase risk of unethical practice associated with partnering. Any allegation of corruption within a SHA procurement process would have serious detrimental effects on the HA. Caution and transparency is required to ensure corruption does not enter the partnering arrangements.

2.4.10 Over powerful Partners

Bennett and Peace (2006) emphasised that powerful partners dictate terms and conditions of the partnering arrangement to marginalise partnering organisations which are dependent on future continuity of work. SHAs must lead by example, demonstrating fairness and trustworthiness, effectively communicating and ensuring initial performance targets for continual improvement are not adjusted.

3 Research Methodology

This conference paper has been assembled on the basis of an extensive review of the existing literature. The publications include academic journals, government reports and books. Naoum (2007) identified that a literature review attempts to integrate what others have done and said, and criticise previously scholarly works, to build bridges between related topic areas, and/or identify the central issues in a field. In agreement, Fink (2010) suggested that a literature review enabled a systematic, explicit and reproducible methodology for identifying and synthesising the existing research conducted. The review of literature focuses on the necessity for Scottish Housing Associations to achieve VFM. The paper considers partnering as an appropriate procurement method to facilitate the VFM objective, through considering historic benefits and limitations. This paper will enable the conduction of further research to test the validity of the historic benefits and limitations, within the specific context of SHA clients. Understanding if partnering will increase the likelihood of achieving VFM through identifying the historic benefits applicable to SHA, could prevent a tempting reversion to traditional procurement during the difficult economic climate.

4 Findings and Discussion

This paper was solely based on a review of literature associated with SHAs and the utilisation of partnering to achieve VFM. The literature primarily highlighted the necessity for SHAs to achieve VFM for both new build and maintenance construction projects. The Housing Minister in the Scottish Parliament, Alex Neil Scottish Government (2010), emphasised the necessity for SHA's to achieve VFM to underpin the future investment in housing development. The Scottish Housing Regulator (2011) reported that in 2004/05 the proportion of HAs housing assets that was funded from Housing Association Grant (HAG) and other capital grants was 73.1%. At the end of 2009/10 the HAG had fallen to 68.0% (2008/09, 69.4%). The reduction in funding illustrates the increasing requirement to which HAs have utilised private borrowings, as well as their own internally generated reserves, to continue to grow their asset base. These circumstances clearly highlight the need for SHAs to procure projects as effectively as possible to achieve VFM. The paper attempts to identify if SHAs should persevere with partnering to achieve VFM, through assessing the validity of the generic and historic benefits and limitations within the specific context of SHAs. The potential resurgence in use of traditional procurement, to receive the lowest price tender, exacerbated by the economic conditions could be justified, should the limitations be more prevalent in HAs partnering arrangements than the benefits.

Upon reviewing the literature, extremely attractive historic benefits for the client through implementing partnering were identified. The three significant benefits were directly related to outcomes of VFM, namely effective cost control, effective time control and improved quality. There was a general consensus within the literature that all three of these benefits can be achieved by the client through utilising a partnering agreement. Two generic benefits that could significantly facilitate the VFM remit for SHAs were reduced administration costs and improved overall satisfaction. According to The Scottish Housing Regulator (2011) lettings costs (costs of owning and managing houses) for Housing Associations was £771.9m with approximately 82% of the lettings costs attributable to management and maintenance activities. This substantial sum

highlights that SHAs could seriously benefit from receiving reduced administration costs. Improving the overall satisfaction of tenants would add to VFM and also adhere to SHAs dedication to supplying quality and affordable accommodation to tenants. The findings emphasise important benefits for the client, which if applicable to SHAs would increase the level of VFM and optimise the investment for capital for necessary projects.

The historic limitations of partnering were also identified. Increased interdependency and increased complacency were commonly viewed as serious limitations associated with partnering. Other important limitations were the inequitable distribution of risks, early commitment of resources and loss of competition. These limitations could be particularly applicable to HAs as risks are inherently passed from the public sector to the private sector, HAs resources are scarce due to cut backs, and HAs must be seen by the tax payer as receiving competitive prices. Should a significant number of the historic limitations of partnering be applicable to SHAs, then serious consideration must be given to the most effective procurement method to achieve VFM.

The findings within the literature review indicate the potential benefits associated with partnering significantly outweigh the potential limitations. However, the literature highlighted various barriers associated with the characteristics of public or quasi-public sector that could be argued will prevent the historic benefits being achieved. This included: protecting the taxpayer against anti-competitive behaviour (Fisher and Green, 2001); procedures implemented by the Public Sector can often work against the mutual trust and open relationship (Woodrich, 1993); HAs may also be prevented to applying an agreed share of savings with the contractor (Housing Forum, 2000); lack of experience associated with both the purchaser and provider of long term partnership arrangements (Burnes and Coram, 1999); and the risk-averse nature of Public Sector organisations, which is embedded within the ethos (Burnes and Coram, 1999). The barriers highlight that some of the limitations could transpire in HA partnering agreements, namely: corruption, decentralised decision making, inequitable distribution of risks, early commitment of resources and loss of competition. Should the research identify that HAs are faced with these limitations, then perhaps the current economic climate would dictate the opportune moment to revert back to traditional procurement. The reviewed conceptual benefits and limitations that may manifest in Housing Association partnering agreements are illustrated in Figure 1.

Figure 1. Conceptual Benefits and Limitations of Partnering

Despite the aforementioned barriers and potential limitations of partnering, the reviewed benefits that can be achieved by the client, highlight that partnering could significantly enhance VFM. The benefits of partnering concur with the SHA need to demonstrate VFM. It is therefore considered that should the future research highlight that the historic benefits of partnering are received by HAs, facilitating the achievement of VFM, partnering must be implemented. The identified barriers would therefore be overcome, ensuring a successful partnering agreement. The emphasis from the Audit Commission (2008) that savings per house can range from £1.66 to £220.00 through more effective procurement, highlight the need to clarify the benefits of partnering for SHAs. If the potential benefits are achieved by SHAs, any reversion to traditional procurement would be unjustified. To assist SHAs achieve the theoretical benefits of partnering, there are change management initiatives that can be introduced. SHAs should ensure pre-requisites for partnering arrangements such as mutual trust, effective communication, and commitment between partners are all present within the arrangement. Management must also introduce continual evaluation and improvement processes, through benchmarking, to monitor performance of projects and identify areas for improvement. SHAs should also utilise partnering workshops to ensure all parties fully understand the requirements of the partnering arrangement and also encourage effective communication throughout all stages of the project. SHAs that embrace the culture of partnering, implement the necessary pre-requisites and processes will increase the probability of achieving the conceptual benefits of partnering, therefore could ease the effects of reduced investment and better utilise the resources available.

5 Conclusion and Further Research

The economic climate has reinforced the need for SHAs to achieve VFM for both new build and maintenance projects. Delivering socially owned rented housing or maintaining existing stock is an important and necessary function within society. With reduced funding from the Scottish Government and the necessity to provide affordable

housing, SHAs must utilise the most effective procurement method to deliver VFM. For a long time, partnering has been advocated, with the historic benefits being widely publicised. This paper therefore attempts to summarise the generic and historic benefits and limitations of partnering, to enable the validity to be tested through further research within the specific context of SHAs.

At this stage of the research, it would appear that should SHAs receive the historic benefits of partnering, then a reversion to traditional procurement and lowest price tenders is unjustified. Confirming the benefits of partnering for specifically SHAs, in future research will provide more confidence to SHAs that they are utilising the correct procurement route. The perceived barriers associated with public sector or quasi public-sector partnering could also be disproved, should the data support the legitimacy of the historic benefits of partnering. The current economic climate emphasises the importance of understanding if partnering is effective, as the low tender prices submitted may tempt SHAs. The findings of the paper highlight that clarifying the benefits or limitations applicable to SHAs that utilise partnering is required due to the necessity for SHAs to achieve VFM and the reduced funding. The current economic climate reinforces the need to confirm if SHAs should continue or discontinue utilising partnering agreements.

Frameworks Scotland – Making NHSScotland a Best Practice Client?

David Manase¹ and Stuart Brown¹

Abstract:

The UK construction industry has been the subject of many key industry reviews, audit reports, and recommendations as to how it should improve. Many clients have embraced the recommendations, developing innovative partnering approaches to deliver their capital investment programmes. The NHS, particularly in Scotland, has often been considered to be lagging behind in the development of modern and innovative procurement routes for publically financed capital healthcare projects. In November 2008, NHSScotland launched Frameworks Scotland as a response to the key industry recommendations and various criticisms over traditional procurement arrangements. NHSScotland has developed Frameworks Scotland as a strategic, flexible and collaborative procurement route for the design and construction of capital projects. This paper sought to identify whether NHSScotland is likely to improve towards becoming a best practice client through the implementation of Frameworks Scotland. A thorough literature review of the subject was conducted. Furthermore, sections of key Scottish industry stakeholders in construction procurement were interviewed. The findings in this research in this paper are that in order for NHSScotland to improve towards becoming a best practice client through the implementation of Frameworks Scotland, the framework arrangements must be effectively managed and nurtured. Furthermore, framework arrangements must be evaluated constantly to ensure value for money and must retain a strong focus on performance management and continuous improvement.

Keywords:

NHSScotland, Frameworks Scotland, innovative procurement, best practice

1 Introduction

The launch of Frameworks Scotland on behalf of NHSScotland followed a lengthy implementation process, of over one year, involving setting up and implementing the framework arrangements, guidance and processes, as well as the OJEU procurement process for appointing the various delivery partners (Health Facilities Scotland, 2008). NHSScotland and the Scottish Government Health Directorates had been considering a national construction framework for some time. The establishment of such a framework had been the subject of an Efficient Government Fund bid to the Scottish Executive in January 2005, which although not taken forward at the time, was the original inception

of developing the framework (NHSScotland Property and Environment Forum, 2005). Subsequent to this bid, the Scottish Executive decided to use an NHSScotland scheme to pilot the principles of the NEC contract, supply chain management and collaborative partnership working and open book arrangements. A £50m refurbishment scheme in NHS Fife was selected and delivered on this basis. This was subsequently reported on, and its success paved the way for the commencement of a national construction framework in NHSScotland (O' Keefe, 2007; Health Facilities Scotland, 2007).

A substantial review of NHSScotland procurement took place, which considered heavily the framework approaches already developed by the NHS in England and Wales. This included a series of partnering workshops, which resulted in the production of a discussion paper on NHSScotland construction procurement. This paper recommended the establishment of national frameworks as the best way forward. The differences in the construction market in Scotland meant that it was deemed more appropriate to develop a bespoke solution for Scotland however using the knowledge, experiences and lessons learned from the other United Kingdom health organisations (Health Facilities Scotland, 2007). Health Facilities Scotland (2008) states that Frameworks Scotland is intended to be a long term, strategic and flexible framework procurement approach which relies heavily on the principles of partnering and collaborative working for the delivery of both new build and refurbishment healthcare facilities in Scotland. Frameworks Scotland uses the NEC Engineering and Construction Contract 3rd edition for construction projects. When implemented, it was anticipated that Frameworks Scotland could be used for an estimated annual NHSScotland capital expenditure of £100 - 150 million (Health Facilities Scotland, 2008). However it is now believed that this range could be significantly exceeded due to the initial uptake of the framework from the health boards.

Scottish Government (2009) states that although not considered mandatory, Frameworks Scotland has been established as the preferred approach to the procurement of publicly funded construction work within NHSScotland and must be considered in the formulation of any business case. Frameworks Scotland is expected to complement other procurement initiatives for the delivery of health facilities in Scotland such as the HUB initiative for procurement of primary and community care facilities (Scottish Government, 2009). Health Facilities Scotland (2007) states that Frameworks Scotland is designed to improve programme and process efficiency. Under traditional arrangements, NHS Boards will assemble a bespoke design team (following OJEU) to progress through Initial Agreement (IA), Outline Business case (OBC) and then Full Business case (FBC) before advancing to design and then tender stage, before a contractor can be appointed to mobilise and start on site. On some projects this full process may take years. Under Frameworks Scotland, NHSScotland clients can dispense with the consultant procurement stage, the design stage and the tender stage. In addition, 70 -80% of the design is done at FBC stage and construction can start on site shortly after approval of the FBC. The early appointment of a delivery partner, and overlap of design and construction activity is therefore expected to save significant amounts of time on each project.

Frameworks Scotland was intended to improve project management of NHSScotland capital projects through a more standardised approach, better clarity of roles and responsibilities, training and skills development, and introduction of a collaborative contract mechanism, which encourages, rather than restricts, good project management

(Health Facilities Scotland, 2008). Frameworks Scotland places a significant focus on value management and risk management within the construction project environment and these are considered integral to the overall process (Health Facilities Scotland, 2008). The ability to appoint a Principal Supply Chain Partner much earlier in the process than under traditional procurement, is considered highly beneficial in relation to joint and collaborative risk management, as well as in maximising value for money within the required budget (Mosey, 2009). In addition, it is felt that working repeatedly with the various health boards will allow the supply chains to gain a better understanding of the clients requirements and build stronger working relationships which will ultimately improve the design and construction quality of NHSScotland healthcare facilities (Architecture and Design Scotland, 2009). The ultimate aim of Frameworks Scotland is to embrace the principles of partnership and collaborative working and ensure that teams within and between the public and private sectors work together efficiently and effectively. This approach is intended to deliver ongoing tangible performance improvements due to repeat work being undertaken by the supply chains and ultimately make NHSScotland a best practice construction client (Health Facilities Scotland, 2008). This aim in the research in this paper was to seek to identify whether NHSScotland is likely to improve towards becoming a best practice client through the implementation of Frameworks Scotland.

2 Research Methodology

The key purpose of this methodology was to set down the principles and procedures of the logical research process that has been undertaken to analyse whether the Frameworks Scotland initiative is likely to make NHSScotland a best practice client. Based on the literature review a number of key themes were developed as follows:

Obtaining better value for money through improving time, cost and quality on NHSScotland construction projects through long term strategic partnering with consultants and contractors.

Improving relationships and reducing adversarial cultures through partnering.

Improving the results of scrutiny and audit into NHSScotland capital projects.

Standardisation of contracts and appointment terms.

Improving design of healthcare facilities and briefing within NHSScotland capital projects.

Management of the framework and partnering arrangements being key to their success.

Improving structures and communication processes throughout NHSScotland capital projects.

Improving project management through guidance and use of the NEC form of contract as a project management tool.

It was recognised that there is a degree of overlap in relation to some of these themes, however this was expected due to the nature of the subject and the linkage and

convergence of the key issues. A series of interview questions was developed, totalling 17 questions, each of which addressed an aspect of one or more of the identified themes.

2.1 Research Interview Participants

The primary source of information relates to the views and opinions of a selection of key industry personnel associated with, or with knowledge of, the Frameworks Scotland initiative. Five interviewees were selected based on their knowledge and experience of the research subject area. A brief professional profile of each interviewee is listed in the table below.

Participant	Role and Experience
Interviewee A	an Assistant Director with responsibility for Property and Capital Planning within NHSScotland Health Facilities Scotland. He is responsible for providing support and guidance and also for development of best practice initiatives relating to property, capital planning, construction procurement and estates management.
Interviewee B	an Operations Director (Technical Advisor and Project Management services) within a national multi-disciplinary construction consultancy. He has almost 20 years experience in Quantity Surveying, Project Management, PFI Technical Adviser, and Fund Monitoring of construction projects working primarily in the health and education sectors.
Interviewee C	Principal Estates Advisor within NHSScotland Health Facilities Scotland. He has over 30 years experience working in Quantity Surveying, Facilities Management, and Estates and Construction Consultancy.
Interviewee D	a Senior Project Manager within a national multi-disciplinary construction consultancy. He has 15 years experience working in Project Management, Quantity Surveying, Risk and Value Management, Property Strategy and in the provision of technical and strategic advice to clients including NHSScotland.
Interviewee E	a Principal Architect within NHSScotland. He has over 40 years experience mainly in the private sector as an Architect, Project Manager, Employers Agent, and Director responsible for Independent Certifier services within a national construction consultancy.

3 Findings

In order to achieve the aim of the research in this paper, the analysis was focused on the key improvement areas that the literature review demonstrated were expected from the implementation of a strategic partnering or framework procurement initiative and included some of the following:

3.1 Improving Relationships and Reducing Adversarial Cultures

Throughout the literature review, partnering and framework arrangements were identified as being based on reducing conflict, adversarial working, and contractual or commercial approaches to delivering projects. ProCure 21 was shown as an example of how this had been achieved in practice with many clients using the same delivery partner for their entire project portfolio. The literature review also identified that the NEC3 form of contract is based on parties working in a spirit of mutual trust and cooperation, sharing problems and risks, and working together to achieve the optimum benefits and objectives of the project.

The interviews identified that working relationships should improve due to client and delivery partner working together over a longer term, as they will each develop an understanding of the other organisations approach, culture and method of operating. The NHSScotland clients would be likely to gain efficiencies from working with the same partner as the partner would take less time and resource to gain an understanding of the clients organisation and priorities, resulting in reduced costs. With regard to the delivery partners, the incentive of repeat business and security of work over a long term period was considered to be a major contributor to ensuring good relationships are built and maintained. A key point emerging from the interviews was that delivery partners will gain an understanding of their client's way of working and be able to contribute to their business planning and overall strategy. This is considered to be a major advantage and a key element of best practice. In addition, it was noted that while improved relationships are a positive development, relationships should not develop into 'cosy' arrangements where the business relationship is less influential and the client eventually begins to take ownership of risks that they are not best placed to manage.

A further point in relation to reducing the adversarial nature of the construction industry and improving relationships, is that within Frameworks Scotland, competitors, on the main Principal Supply Chain Partner frameworks as well as the Professional Services Contract frameworks, are encouraged to participate in information sharing forums and network groups, which are set up and administered by Health Facilities Scotland. Each organisation is expected to share experiences, lessons learned, and examples of best practice. Under traditional procurement arrangements this would not be possible as organisations would wish to maintain corporate confidentiality, however they participate in the Frameworks Scotland forums on the basis that they will, or should, be awarded a fair share of the available workload and do not need to maintain the same level of competitive edge. This ultimately results in experiences gained from each individual project, being shared among all organisations, which allows continuous improvement to be exponentially increased.

3.2 Standardisation of Contracts and Appointment Terms

The literature identified that Frameworks Scotland will utilise a standardised contract form and consultancy appointment terms for all projects. This is considered to be advantageous due to the known division and allocation of risk. The interviews identified that this element of standardisation would provide a better understanding for all parties of roles, responsibilities, and liabilities on NHSScotland construction projects. In addition, it was noted that the standardised contract forms and appointment terms would greatly assist less experienced clients and smaller health boards who are less familiar with major capital projects. The interviews also noted that there was significantly less scope for misunderstandings between the contract parties, if the same terms and conditions are being used on a repeat basis. This ultimately reduces commercial risk for delivery partners and should therefore improve value for money and openness in relation to contractual issues.

There was one issue raised within the interviews in relation to the fact that Frameworks Scotland uses only one NEC3 procurement option, Option C (target cost with activity schedule). It was felt that this could be regarded as inflexible and perhaps overly prescriptive, and may not always be the best procurement option for the particular project. A further doubt was expressed during the interviews about whether standardisation will actually be maintained for the duration of the framework

agreement, as individual NHSScotland clients may begin to make amendments on a single project basis. However the literature review had earlier identified that amendments will require permission of the Frameworks Scotland management team, again stressing the importance of a nationally managed and coordinated approach to the implementation of the frameworks.

3.3 Improving Design and Briefing

The literature identified that it was expected that design of NHSScotland construction projects procured through Frameworks Scotland would be improved through earlier contractor involvement and the overlap between design and construction. The interviews generally concurred with this however there were doubts expressed by one of the interviewees, that the design team being employed by the contractor was not necessarily likely to promote the design elements, in fact it may have the opposite effect due to the delivery partner wishing to minimise costs and also develop a design which is as simple and straightforward to construct as possible. Generally, the interviewees believed that the early engagement of the contractor delivery partner would encourage more innovative design solutions, improved design quality, and better construction techniques on site. There was one particular exception to this trend with one interviewee believing that contractors did not generally provide innovation or different solutions to problems, and it was usually the designers who were most active in those aspects. Both the literature and interviewees agreed that under the Frameworks Scotland arrangements, briefing would be significantly improved and delivery partners and their supply chains would be able to develop a better understanding of client requirements through working closer together.

3.4 Management of Framework and Partnering Arrangements

The literature review identified that a key aspect of developing and maintaining a successful partnering or framework relationship is the management of the arrangements. In the case of Frameworks Scotland, the literature identified that NHSScotland had established a central framework management team following the model used by the NHS in England and Wales. Throughout the interviews there was a broad consensus from all interviewees that the management of Frameworks Scotland was a critical element of ensuring standardisation is maintained, ensuring continuous improvement is possible, and ensuring a nationally coordinated approach is fully maximised, exploited, and the benefits of that approach optimised. In addition, the central management function is also necessary to allow performance measurement comparisons and benchmarking. It also provides an element of consistency across all projects and ensures delivery partner performance and behaviour is being closely monitored, for example ensuring delivery partners are not 'picking and choosing' work within the central belt only and not servicing the needs of NHSScotland in more remote areas such as the highlands and islands. Overall, in general terms, the interviewees felt that effective resourced management of the framework was critical to its ongoing success.

4 Discussion

The aim in the research in this paper was keenly pursued in an attempt to fully understand whether the Frameworks Scotland initiative is likely to improve NHSScotland towards being a best practice construction client. In general, the interviewees considered the development and implementation of Frameworks Scotland

to be a positive development within NHSScotland construction procurement. Improvements in programme timescales and certainty as well as better management of costs and improved value for money were key aspects of this. In addition, from the general perspective of the interviewees, it was expected that the Frameworks Scotland initiative would improve project management, project structures, definition of roles and responsibilities, and standardisation of contracts and appointment terms. The Frameworks Scotland initiative is also expected to significantly improve a number of key issues affecting the design of healthcare facilities including briefing, design quality and functionality, and sustainability. It was generally felt that the effective management of the Frameworks Scotland initiative was a key feature of their ongoing success and contribution to the development of NHSScotland as a best practice client.

A key finding of the research is that over and above the direct benefits of the implementation of a national strategic framework procurement arrangement, there are many indirect benefits related to corresponding NHSScotland initiatives in relation to design quality, sustainability, patient focused briefing, and ward bedspacing and single room initiatives. These significant developments are not directly related to Frameworks Scotland, however are being influenced and driven by the fact that NHSScotland, for the first time, has a nationally coordinated portfolio of construction projects and extensive capital programme which is visible to all NHSScotland clients, delivery partners and consultants. The research has demonstrated with considerable certainty that procurement lead in times will be improved under Frameworks Scotland. The ability to appoint the Principal Supply Chain Partner and Professional Services Contract consultants significantly more rapidly than under traditional procurement or OJEU arrangements, combined with the overlap between design and construction will provide significant overall programme savings. It is also expected that the involvement of the contractor at an earlier stage will improve buildability and subsequently reduce construction programmes, improve programme certainty, and reduce the risk of delays, which is a highly common risk on construction projects. The involvement of a contractor delivery partner from a much earlier stage in the process, as part of an integrated project team, is also expected to significantly improve decision making through availability of expert construction advice to the NHSScotland client.

The research has also indicated that Frameworks Scotland will provide benefits in relation to project costs. While the literature review identified that partnering and framework arrangements are often quoted as providing significant cost reductions, it became clear from the subsequent interview that this was not the primary objective of NHSScotland. The real objective is to improve value for money within defined capital allocations and improved cost reporting and cost certainty through better visibility of risks and improved financial management through open book cost reporting. A key feature of the Frameworks Scotland initiative is the use of the NEC3 form of contract. Generally this is considered a flexible form of contract however Frameworks Scotland is restricting the NHSScotland clients to one particular procurement option, target cost with activity schedule (Option C), which was considered to be one possible criticism. Although this perhaps could be considered restrictive, the research demonstrated that this single procurement route was considered a success on the ProCure 21 initiative, and would also ensure that both NHSScotland and delivery partners were constantly working with the same procurement option, providing a further element of standardisation and also removing any possibility of prolonged discussion or disagreement in relation to choice of contract procurement route. In terms of the NEC3

contract generally, it is widely considered to be a better, more proactive form of contract, expressed in clear understandable language, which encourages more disciplined project management through definitive response times and encouragement of early warning of issues and risks.

In addition it is expected that the introduction of an online collaborative project extranet tool, which provides a storage repository and document management system for all project documentation, and also facilitates the management of the NEC3 procedures, across all Frameworks Scotland projects, will be a significantly positive development and is a modern innovative client led approach to best practice management of projects. The research has shown that there are significant precedents in relation to the framework and partnering approach being successfully utilised as a best practice model by other client organisations including the NHS in England and Wales. It was however noted that one of the pioneers of the framework approach, British Airports Authority (BAA) had recently announced that their frameworks were to be discontinued and replaced by other procurement options. The research demonstrated that many private sector clients may follow this example and take the view that they can secure better value for money using lowest price tendering or alternative procurement routes during this current recession and financial climate. The research did however demonstrate that best value for money is not always achieved through obtaining the project for the lowest cost.

The construction industry has been significantly affected by the current recession and many clients are being forced to cancel projects or put projects on hold due to the uncertainty or unavailability of previously secure funding streams. NHSScotland has the considerable advantage of being able to guarantee a steady flow of construction workload with a reasonable degree of certainty and is not subject to the same issues affecting their funding streams due to the known availability in advance of public capital and highly politically driven spending on healthcare. Emerging from this was the issue of the improved understanding of roles and responsibilities on NHSScotland projects. The research demonstrated that the Frameworks Scotland initiative would provide much more clarity in relation to the roles and responsibilities procured through the standardised framework contracts. The research also identified that it was expected that NHSScotland would become a more informed client, with a significant ‘corporate memory’ and an improved contractual knowledge and understanding. It was therefore expected that NHSScotland would become a more informed and better construction client, and this would improve relationships with private sector partners.

5 Conclusion and Further Research

Overall this research concludes that the Frameworks Scotland initiative is a major step by NHSScotland in improving as a construction client. NHSScotland is rapidly improving in terms of project management skills, contractual awareness, and understanding of risk within the construction project environment. At the same time, NHSScotland is becoming more design focused comprising functionality, aesthetics, sustainability and patient environment focused design. In addition, NHSScotland is becoming more performance focused and accountable in terms of value for money, which requires a greater degree of cost certainty and transparency that Frameworks Scotland will provide. Frameworks Scotland is a major development for NHSScotland in striving to become a best practice client, however it is essential to realise that this

initiative is only one aspect of the clients wider procurement strategy. The consideration of the strategic fit of Frameworks Scotland with wider NHSScotland and public sector procurement initiatives will therefore be an important factor in maintaining a holistic best practice approach. Frameworks Scotland will only be effective as a best practice model if it is effectively managed, continuously improved, embraced by the construction industry, and shown through robust and accurate performance measurement to provide real tangible improvements in time, cost and quality. The initiative certainly represents an adoption of best practice for NHSScotland based on the various criticisms, recommendations and findings of key industry reports, however in order to maintain a measure of best practice it will be vital to continue to improve value for money on construction projects through an increased focus on delivery partner innovation, risk allocation and management throughout the integrated project teams, and better design quality and functionality of healthcare facilities, ultimately improving patient care.

Climate Adaptation and Resilience on Construction Sites

Rosemary Fieldson

Simons Group Ltd

991 Doddington Road, Lincoln, LN6 3AA

Email: rosi_fieldson@simonsgroup.com

Abstract:

Predicting the possible effect of climate change on the climate of any given country is a complex and uncertain science. The construction industry in the UK historically has used programme planning and risk analysis methods to absorb the effects of variable and adverse weather on building contracts and depended upon and experience of construction professionals to assess health and safety risks posed by weather events on construction sites to prevent the occurrence of injury, damage to property or deaths. The evidence from climate change models suggest that in the short term variability and extremes will be more common whilst in the longer term, cold weather impacts may reduce as the climate gradually warms. This paper seeks to understand the impact this may have on construction programmes and project management and understand how the UK construction industry may prepare for and overcome changing climate in managing construction programmes and contracts.

Key Words:

climate change adaptation, resilience, construction industry, risk management

1 Introduction

Belief and understanding in the issues and science of climate change and warming patterns within the construction industry at consultant level is generally thought to be high. However lack of trust in long term weather forecasting and imperceptible or gradual change in UK climate may prevent a full recognition of the need for climate change adaptation and resilience. Add to this the dependence on past experience of individuals and teams in planning and site management tasks and management and there is significant potential to be at the mercy of the weather with associated risks under-anticipated. The definition of adverse weather use in the construction industry is: *weather in which operations are generally restricted or impeded.*

Using a study by Ipsos-MORI, Pidgeon (2011) claims that extreme weather influences behavior more than climatic change due to the more apparent social and economic impact felt by communities and businesses affected and having felt such impacts changes perception of climate change. Recent cold weather events in the winters of 2010 and 11 in the UK and possibility of reversed weather systems over the UK causing colder winters and drought summers may be changing perceptions of weather related risks and impacts on site and to construction programmes. Whether the projections of

scientific modelling of climate change or the experience of extreme weather disruption on sites is more likely to be utilized to plan and prepare for construction works is not clear and may rely on individual judgment. Both may be needed to influence the industry for social and economic resilience in the future and contractors need to be able to reduce health and safety, business and performance failure risks posed by future weather and climate.

1.1 Aims and objectives

The aim of the paper is to identify how contractors will need to adapt to future climate change impacts in site operations and supply chains and what impact this may have on ability of the main contractor to deliver projects safely, on time and budget.

To understand the impact of weather experienced during construction on health and safety, programme and building performance.

To understand how the supply chain will be impacted by less obvious and longer term climate change and how this could change the design and procurement of buildings in the future.

To develop recommendations for resilience planning in the supply chain of buildings, and means to advise customers of the construction industry on what to expect and how best to procure buildings in the future.

The paper intends to conclude on how best practice in project management should anticipate and respond to weather pattern and climatic changes predicted in the UK towards minimizing the impacts for the construction industry, its supply chain and clients.

2 Literature Review

Research published by the UK Climate Impacts Programme (UKCIP) is readily presented through maps depicting probability of increased temperature and rainfall until 2080. These include an expectation of milder winters, wetter summers, prolonged heat waves and increased wind loading. Changes are perhaps more pronounced in the south east and may affect cities differently than rural areas. Together these changes would impact on the performance of building services energy demand, structural stability from storm damage, ground stability and the risk of inundation from flooding. This science is generally accepted in that UK government recommends that climate will now change regardless of whether emissions rates can be capped or reduced (DTI, 2010). This acknowledgement may need to prompt changes to building performance standards to respond to how weather and climate might change over the lifetime of buildings to be constructed in the near future. It is not clear from the climate research if the UK climate will modify over time to be more like that of another more southerly maritime country or region and whether experience and building typology materials, construction methods and building services technology from these places can be drawn on effectively or not.

Government recommendations provide a view towards opportunities for businesses to exploit by embracing the challenges and seeking out market gaps in this predicted future (DEFRA 2010). Other recommendations identified by the UK Climate Impacts

Programme (BACLAIT, 2010) have provide an overview of risks and opportunities from the vulnerability of the supply chain and logistics, impacts on customers and clients, changing behavioural patterns, risks of building performance failure and also the risks of management either under-preparing for change or overreacting to a perceived threat which may remain statistically unlikely.

Advice for design of buildings for changing climate is well served by the literature at community level and at individual building level (Shaw, Colley and Connell, 2007; Gething, 2010). Many of the technologies offered centre around well known technologies such as rainwater harvesting, Sustainable Urban Drainage (SUDS), passive solar design and use of the thermal and evapo-transpiration and microclimate modifying features of materials and landscaping. These design modifications are often compatible with reduced resource availability. Refurbishing existing buildings is another important area. Advice centres round using scenarios, developing resilience and flexibility from the scenario findings and regularly reviewing mitigation plans at all levels from household to governmental.

The Confederation of British Industry(CBI) have published a very informative guide (CBI, 2010) for businesses and claim that while 87% of FTSE 100 businesses accepted that they were at risk from climate change, only 35% had responded with a strategy or taken action. This research raises cost and availability of insurance, damage to reputation and ability to achieve compliance as additional risks for businesses too consider. An approach similar to strengths, weakness, opportunities and threats analysis (“SWOT”) is proposed of assessing businesses’ Supply chains, Markets, Assets, Compliance, Operations and Reputation (SMACOP) to scope issues followed by a risk management exercise to develop resilience. Key conclusions are that businesses may be under-informed of the likelihood and risks posed and tend towards a reactive rather than proactive approach to planning for more difficult conditions.

The need for reliable data is clear, and whilst an excellent resource at national level UKCIP (2010) does not help in the planning of individual projects in specific locations. Nor does it help to predict the changing markets for materials and labour in the construction industry which may be directly affected by climate change (such as closure of untenable quarries or factories in coastal/fluviat regions due to flooding) but also indirectly such as the possibility pricing branches of multinational companies out of the UK as a result of the Carbon Reduction Commitment or CRC Energy Efficiency Scheme in the UK (DECC, 2011).

Research by Frith and Colley (2006) suggests a fear of limiting economic potential being used as a reason by many businesses for inaction. A lack of data which can be applied effectively also limits the ability of businesses to make reasoned judgements. They identify that the impact of a sudden financial shock caused by a weather event can be extreme and that adaptation planning is critical for business continuity. Whilst each industry is singled out for specific risks and expectations of impacts, it is clear that all sectors are interrelated with each other; infrastructure networks, transport and utilities being fundamental to the ability of all sectors to be successful, retail sales affecting industrial and agricultural demand for products, the construction industry being depending on these sectors to generate workload too. Dlugolecki (2009) notes that smaller businesses are more at risk from sudden weather impacts, furthermore some sectors are very sensitive to prolonged and unseasonal weather variability such as

tourism and farming. These sectors need to be seen holistically to accept the interrelation that exists.

3 Research Methodology

The aim of this paper was to understand the situation for a main contractor as the first point of view of the risks, threats and opportunities posed by climate change. From a position within a main contractor organization a number of means noted in the literature have been applied as follows to understand the aspects relevant to office locations in the UK;

Cause based impact analysis of individual issues

Business vulnerability and opportunities approach using the CBI method (SMACOP)

Scenario Planning; establishing what could or should happen if an event occurred to protect people and property

Catastrophe modelling (Dlugolecki 2009) which takes up a sequence of events in succession or together to identify costs or impacts in quantifiable terms.

Typically the business of a main contractor comprises utilizing a supply chain to deliver multiple buildings for a number of clients in a wide variety of geographical locations. The risks are therefore balanced between the demands and expectations of the client organization and their economic drivers and the delivery limitations and vulnerability of the subcontractors and materials manufacturers which form the supply chain working at a specific site.

A workshop was set up with a selection of invited subcontractors to draw on their experience and view point regarding the type of work they typically encountered. The participants were asked to consider what happens on site when certain extremes of weather occurred such as performance failures of materials, how programme might be affected and health and safety issues which would need to be considered. They were asked to use experience they had on large new build projects in the UK (between £1m and £50 million). They were also asked to consider the likelihood of defects and performance failure in the longer term due to conditions encountered during construction which might occur. The subcontractors included specialists for earthworks, groundworks, steel and timber structure, roofing, flooring, electrical, mechanical, internal fitout and decoration. The causes were identified as;

Higher summer temperatures (hot and dry)

Higher summer rainfall (humidity and flash flooding)

Cool humid conditions

High wind speeds and storms/tornadoes

The subcontractors also considered catastrophic events with compounded causes such as forest fires/fire risk and water shortages in hot dry conditions. Exceptionally cold weather and snow loading was not asked to be considered as part of the exercise due to

the recommendation of the research presented from UKCIP. The group was split into groups and asked to review causes based impact analysis consequences and offer possible adaptation and mitigation measures in groups covering their own specialism (structural systems, groundwork, flooring, envelope and retail interiors and refurbishment). The groups came together to review their findings, spent some time considering their own business using the SMACOP approach and then discussed the use of scenario and catastrophe modeling methods.

4 Findings and Discussion

Many of the participants had experienced some of the causes and impacts raised either in the UK or in other climatic regions and found it easier to express their understanding or concerns using anecdotes than to envisage future projects of which they had no experience. Scenario planning was easier to perform for an identified site (with apparent constraints and hazards) than in abstract discussions. During the workshop it was noted that participants did not attempt to document the CBI SMACOP method in any detail and may have preferred taking this approach back to discuss internally rather than discuss in an exposed environment with competitors. Feedback received by the researcher following the workshop would suggest this was the case. In the workshop it was difficult to maintain focus on methodological approaches outlined as each participant responded differently to the realization of likelihood and notes have been taken by the researcher of general discussions instead as listed in Table 1.

The primary concern was that the main contractor must not allow activity to continue at risk of injury or death to operatives and members of the public. Consequences of safety risks were generally well understood and the group felt that they had benefitted from gaining some understanding about risks in specialist trades that they weren't normally interacting with on site. Both main and subcontractors need to keep good records of site and weather conditions in site diaries, site management have a duty to display weather forecast notices. Subscription to a weather service, and use of locally fixed electronic monitoring devices and anemometers would assist with this.

Subcontractors must understand how weather may affect all risks in any activity and ensure these are included in both subcontractors and general written risk assessments, especially limits and thresholds at which any particular activity must cease and who makes the decision to cease work. Site management need to have a full understanding of possible weather issues involved in risk assessments of each activity. The wind speed at which safe lifting is limited varies for different cranes and products, and is outlined in guidance BS 7121-3:2000 and in individual manuals for lifting equipment. Hand held and crane mounted anemometers must be used to gauge wind speed frequently both prior to and during lifting works. The crane operator usually makes the final decision based on his experience but advance notice of windy weather could stop the crane operator from being put at risk too (BS EN 14502-1:2010).

Table 1. Findings of participant discussions (cause based impact analysis)

Cause	Performance issue	Consequence	Possible mitigation or adaptation
Too wet	Inability to excavate effectively	H&S risk of subsidence and slumping of trenches	Avoid low lying sites with unstable soils
			Avoid deep trenches in the design
			Sheet piling design and retaining structures
		Programme is effected	Timing of work to avoid rainy season
			Allowing sufficient programme float when rainy seasons are unavoidable
		Additional materials required to fill less effective cuts	Cost of materials/over-design
	Inability to apply walling materials such as render in falling rain	Programme and critical path for enclosure of the building	Allowing sufficient programme float when rainy seasons are unavoidable
	Flooding on site	H&S site closure	Cost of programme delay
		Mess and spoiling from flood water	Additional works for repair/replace damaged, stained and spoilt works and cleaning
		Latent defects	Cost of correction
	Flooding of site access or near to site affecting staff travel	Site closure	Consideration of plan to ensure workforce can evacuate safely
		Inability to complete specialist tasks	Ensure alternative team members have adequate skills and experience to cover absence
	Flooding of main logistics routes or loss of infrastructure (i.e. bridges) for deliveries	Delay to works awaiting materials or equipment	Programme delay (using example of loss of bridge in Cumbria in November 2009 could have been a prolonged delay)
Too Hot	Humidity affecting application and drying time of finishes Cool humid prevents curing and bonding of adhesives. Hot and humid prevents drying generally	Delay to programme and risk of defective work.	Programming works to allow sufficient time to dry
		Severe performance failure (for example intumescent paint, adhesives, mastics)	Eliminating dependence on seals and paints for integral performance through design
	Solar radiation falling on roof	Albedo effect on reflective roof materials causing heat traps, and fire risk	Consider reflectance and absorption of under layers as well as final build up of roof in the design
		Heat build up on black and dark absorptive finishes (melting of products or failure to seal joints)	Alternative materials in design
	General site exposure (glare, sunburn,	Conditions can be fatal and temporary effects could	Salt tablets, sun cream, and availability of water, enforced

	dehydration and sunstroke in workforce)	lead to a serious accident, error of judgment	shade breaks. Putting on more clothes as protection against hot air reaching the body.
	Overheating inside a fully airtight building where other cooling/ventilation controls and systems are yet to be installed	Heat exhaustion	Anecdotal evidence of all works stopping on site at 43°C in the Middle East and holiday period (such as in European Summer) avoids worst extremes.
		Overheating due to exothermic action and inability to cure concrete slabs properly	Planning for controlled ventilation to enable drying
	Differential solar gain through windows and roof lights	Patchy and poor curing of screed, slabs and bonding, fading of floor finishes, especially in large floor plate buildings	Change roof light orientation, material or design.
	Concrete cures too quickly	Cracking and possible latent defects	Anecdotal evidence of use of ice in middle east to slow down concrete curing
			Use of PFA and GGBS and other retardants to slow curing
Too Dry	Dust creation from dry exposed ground	Nuisance caused may result in compulsory site closure	Damping down adequate water supply required
	Concrete supplier difficulties due to water pressure or shortages to non essential services	Impact on programme	Theoretical risk - This had never been heard of by the group as such water shortages had not yet occurred in the UK
	Risk of fire on site or from adjacent sources of fire such as buildings, trees and hedges	Safety risk	Fire plan to assess nearby risks and ensure location of source of water identified and available if fire service have to pump in more remote sites
		Damage to building works - Cost and programme affected	Insurance protection against fire from outside
			Damping down of desiccated vegetation
Too Windy	Inability to lift materials by crane beyond safety thresholds	Programme delayed	Unit sizes of pre-fabricated items and crane sizes planned to minimize risk
	Working at height and exposed sites with sheet materials	Risk of wind destabilizing workers and hand/arm injuries	Avoid manual lifting of sheet materials through design and method statements
	Working at height generally	Unsafe for workers, risk of injury. Delay to programme	Monitoring of weather forecast by site management to prevent works starting or exposing fabric at high level
	Instability of hoardings, scaffolding, fixed platforms in high winds	Loosened boards and poles cause hazard workers and public and damage to	Ensure design will withstand windspeeds and checking demountable hoardings and

		property	scaffold regularly
	Partial and exposed works	Vulnerable to wind damage	Protection and programme planning to limit exposure
	Roof damaged by exceptionally high winds during programme	Consequential loss to internal works already completed	Suitable safety factors designed into roof design and detail of flashings etc
		Disproportionate collapse in partially constructed buildings	Protection against consequential loss
	Commissioning of roof level plant delayed	Programme delay if critical to opening etc	Better planning of specialists visit
Combination events and storms	Wind driven rain egress into building and partial completed envelope	Damage to internal finishes	Protection and programme planning to avoid exposed fabric
		Undetected interstitial damp causing latent defects	
	Deliveries affected by shipping delays and port closures	Programme delay, possible loss of special materials by sinking of a vessel	Protect against risk through insurance
	Staff turnout late/no-show for work	Team of specialists installers/engineers are delayed in the same vehicle	Lodge staff locally to site or employ regionally scattered workforce, ensure adequate training is given to spread specialist skills throughout workforce
	Fires from offsite driven by wind	Loss of materials, damage to building and safety risk	Assess local surroundings and have plan in place
	Weather forecasting (week ahead) becomes erratic and inconstant	Inability to plan in the short term for thresholds being breeched for lifting etc	Utilise links to weather websites and weather warning alerts
			Put back up plans in place for special tasks such as lifting operations
	Dust blown onto site from elsewhere	Damage to quality of finishes	Assess local surroundings and have plan in place
	Erratic weather across UK/Europe	Far reaching supply chain affected by event far away from actual site	Take account of weather variation in differing locations in the UK and Europe

The UK construction industry has seen very difficult economic conditions in since 2008 and resulting in a wider use of competitive tendering by clients. Contractors may respond to this by eliminating any perceived wastage in programmes and preliminaries (the cost associated with running the site; staff, welfare facilities, hoardings, temporary elements of the building site). Competitively shortening programmes to enable the customer earlier access is common consequently demanding more competitive behaviors from suppliers of materials, subcontractors and specialist installers. These subcontractors in turn will eliminate any spare time in their own programmes to remain competitive, time which in the past would have allowed a buffer against bad weather

and missed deliveries at any time of year. This contingency to allow for adverse weather has become virtually non-existent.

The Main contractor has to make contractual claim for delay due to exceptional weather or suffer Liquidated and Ascertained damages as set out in the contract. The Subcontractor generally has not priced for weather contingency in programme to reduce tender price or has only assumed for typical conditions as averaged over the last 30 years or used more recent experience. If the claim relates to exceptional weather conditions it would be allowable, if the weather was to be expected at that time of year then it is not and the contractor will seek to redress the loss against subcontractors. JCT 2005 suite of contracts points towards mediation or arbitration if the contract administrators' decision is contested in this definition. This is an interesting point as with climate change predictions of increased exceptional weather conditions and unseasonal weather patterns this definition becomes harder to define and will changeover time. Contract administrators may need training or a resource (Meteorological Office or similar) to define this issue. Where the claim is not deemed to be exceptional weather, the Subcontractor bears cost of delay and impact on turnover and may become at risk of insolvency. Subcontractors on the whole felt that weather was a chance thing; three mild and dry weeks in February just as likely as three weeks of solid rain in July, their attitude is to cope and aim to recover quickly. Loss of power and other utilities is much less of a risk than in permanent buildings as sites were used to being self sufficient.

Contractual practice is driving main contractors to continue to test the market and not commit to subcontractors until the very last minute – this was generally viewed as detrimental to building quality and forces subcontractors to cut down prices to a point where adversarial behaviour once delay is experienced is inevitable. This is seen as a vicious cycle. There is lost opportunity from lack of early involvement of specialist contractors to solve problems of conflicting specification and make buildings more resource and energy efficient, and ensure programmes are risk free. Customers need to consider other forms of contract to enable better design stage planning and preparation and anticipate increased cost of building procurement. Increased risk left with the supply chain needed to be balanced with increased customer responsibility.

Main contractors need to be assured that insurable risks are covered; this may have an uplift effect on preliminaries. Subcontractors need to ensure that unexpected costs associated with weather events have been included in their contract with the main contractor to avoid being left undefended against a claim. The Customer needs to be made aware of risks taken on and cost impact in prelims of both main contractors and subcontractors. The client is interested in long term performance for their own gains, but may not be so accepting of increasing costs and programmes, and although UK Construction Design Management regulations expect the customer to take their share of responsibility for health and safety and to provide adequate time and resource for work to be undertaken safely, on a day to day level, this area is much more site focused. Insurers and lawyers have a role to play in advising customers towards better practice.

The Design Team (Architects, Quantity Surveyors, M&E Consultants and Structural Engineers etc) have an interest in performance requirements being met, but may be much less involved in programme planning or sourcing all materials in supply chains. Although safety is paramount in their designs, involvement in day to day site

management is rare. Construction Professionals would be well advised to keep informed of technologies and materials which help to mitigate climate change and be prepared for new design standards in the future too.

Clients and their property advisors must also consider risks in selecting sites for new development and continued occupation of existing buildings. Lease length and mechanical and electrical system design life drives the time frame to 25 years ahead to avoid catastrophic failures which effect inability to trade or loss of stock. Developers and design teams are looking 1- 5 years ahead for designs and responding to site constraints and anticipated legislation changes, whilst the contractor looks only to the duration of weather risk on each individual project until handover.

4.1 Risks and Responsibilities

The workshop concluded that these good practice recommendations should be adopted without delay to limit risks;

Health and Safety – which commenced with discomfort caused by weather conditions and extended to parameters defining when certain works on site must be stopped or the site closed entirely in order to maintain safety of workers and the public.

Additional PPE for heat and solar radiation have an additional cost which is generally borne by the subcontractor. The equipment is however mostly suitable to be re-used for a number of projects and already in general use for roofing trades exposed to high levels of solar radiation.

Consumables (water, salt tablets and availability of quality sun cream); contractors could consider could bulk buying and requesting sponsorship by food retail and pharmaceutical customers of these products.

Main contractors should introduce opportunities for site operatives to have any moles or skin conditions checked by a visiting health care practitioner to raise awareness and identify any skin cancer incidence early.

Additional breaks and “siesta hours” may have a detrimental impact on programme, but workers do tend to take an enforced lunch break of an hour inside a well ventilated cabin already, this could be shifted to a later hour if very hot conditions prevailed.

Daily briefing and reminders by site managers/health and safety representatives to prompt weather report checking and seasonal issues by site teams.

Checking regimes for loose and weather sensitive materials and hoarding which could be a danger in high winds.

Contractual and Commercial – relating to delay and financial impact in the first instance, the complexity of global supply chains and delivery of materials to sites being hindered by weather events as well as longer term changes in where materials were supplied from and what impact that might have on cost.

Being realistic about programme and weather; use longer term predictions of weather but with anticipation of the unexpected patterns and out of season events.

Reviewing sensitive supply chains and lengthy delivery routes for problems and build in contingency.

When severe weather occurs, follow on learning is advisable to build good practice into subsequent projects and avoid repetition of difficulties experienced.

All buildings, construction sites and places of employment would benefit from having a disaster recovery plan (or a less dramatically named incident management plan) which outlines who is responsible and what should be done in the event of receipt of threatening weather reports related events to protect individuals and property alongside fire plans. These should take into account flood risks and impact on access and utilities as well as evacuation triggers.

Disaster recovery planning for electronic information and paper documents helps with compliance and insurance. Protecting stock and fabrication work in progress for off-site manufacture was similarly important to be protected.

Establishing a climate adaptation and resilience planning review process as part of either strategic planning, commercial and insurance viewpoints with senior management level responsibility and commitment to maintain.

All businesses should review the opportunities and threats posed by changing climate and adverse weather events. National investment in rail deliveries, ports, flood alleviation schemes, coastal defenses are needed and these are clearly an area of huge opportunity for the construction industry to secure future workload.

Design and performance – relating to performance of the building at completion and over the longer term to meet the needs of adaptation to anticipated changing climate over 25 to 60 years building design life.

It is important in the short term not to become complacent about cold weather impacts (including snow loading and ice build up) even though some predictions claim that cold snaps will be much reduced in the longer term, they are not impossible.

Anticipate the predicted level of degree days within the lifespan of cooling and refrigeration equipment and future proof the performance specification.

Review the impact of loss of stock, trade or production in buildings which fail to provide the internal conditions needed, this might help to justify additional costs when refurbishing or developing new build projects.

Modification of building fabric design for changing climate may lag behind services design, meaning that the shell is built to building regulations and standards which are out of date already by the time the fitout is completed. Developer's teams may be forced to predict these design parameters to future proof shell building against risk of failure to secure tenants.

4.2 Longer term climate change and catastrophe modelling

The entire group discussed what they thought might be longer term implications for the construction industry, their own supply chains and customers expectations and needs.

Table 2 Longer term issues which could be considered in catastrophe modelling

Issue	Change anticipated	Impact
M&E equipment currently manufactured in China	Economic bubble expected to burst	Manufacture may become more local to the UK
Steel production moving towards location of ore and low carbon/cheap fuel/cheap labour	Recycling drive may lead to more UK localized production	Increased recycled content of steel and reduced carbon footprint but would costs be counter balanced by cost of shipping increasing?
Cost of shipping from overseas	Might get more expensive if storms and hurricanes make port business more erratic and insurance more expensive.	Tendency to source more locally and change design to use locally available products
Peak oil/ failure to deliver oil forcing up oil prices	Increasing all transport costs significantly	Tendency to source more locally
Higher cost of materials due to manufacturing costs increasing	Lifecycles of buildings need to be extended	Could mean less new build work, but more refurbishment
	Attempts to rationalize quantities of materials and reuse more	Less waste and materials to landfill
Current design standards no longer relevant	Wide scale changes to Building regulations and design standards to accommodate higher peak rainfall, wind speeds etc.	Training for building inspectors and structural engineers etc
Infrastructure reinforcement	Large contracts for new flood defenses for roads and rail, national grid, District energy schemes etc	Depends on timing and budget for government led works to be secured
Some raw materials may be in more demand such as renewable and low carbon, special metals for M&E equipment	Costs go up, longer lead-in times	Changes may be needed to decision making process of clients/funds/developers to enable alternatives to be used
Buildings and services integration, pre-fabrication of elements etc	Specialist design needs to be incorporated earlier to avoid added cost and abortive design work etc	May require changes to current contractual and customer procurement programmes to enable design stages to be frontloaded with specialist contractor involvement or design.
Servicing strategies are more complex to manage; renewable energy, BMS, more automation, actuation etc	Breakdowns and seasonal commissioning call backs more frequent	Post occupancy evaluation and remote management becomes a growth area. Quasi-PFI type of management and maintenance contracts with carbon performance targets may become more common

Developing cost projections for these changes was very difficult to consider as so many variables were at play and a team would be needed in each case to agree the timeframe and consider the commercial impact on the client, main contractor, subcontractors and supply chain. It was apparent in most scenarios that cost impact could be beneficial or

detrimental depending on the viewpoint of the organization doing the modeling and consequently the gains could neutralize the losses if enough foresight and planning were in place. The use of other ways to measure impact was also discussed such as carbon emissions, and less tangible sustainability indicators to determine the winners and losers in any given situation.

4.3 Limitations of the workshop approach

It was not intended that this paper considered sustainable design or principles of design for climate change adaptation in detail but it became apparent that the construction processes and supply chain of buildings was so very much interrelated with the design of the building that it could not be ignored. Design and materials selection has such an influence on the risks present in the construction stage and the potential for failure in the building life that any further study must consider these together.

The workshop and survey techniques used took in a small and self selecting sample of the subcontractors involved in the industry and the range of construction areas covered by the attendees was difficult to control to ensure all issues were considered in every aspect of the construction process.

The depth of experience of and response to extreme weather events may be dependant on the age and experience of the individuals involved. Surveying views and opinions of construction work programmers was not undertaken as part of the methodology of this paper, it could have helped to verify the expectation that statistical data and past experience of weather event repetition is used more than forward projection of climate change and learning taken from extreme scenarios. However, this does not change the need for a the adoption of a considered risk approach to respond to likely and foreseeable risks to prevent human and property harm and not over-respond to perceived or over stated risks resulting in commercial harm.

Reviewing the clients approach to the recommendations made has been undertaken with selected customers but for reasons of confidentiality has not been reflected in this paper. It would be fair to say that changing designs and procurement approach to reflect the UKCIP predictions is yet to be adopted. Furthermore it will take many years before actions could be proven to have been beneficial.

5 Conclusion and Further Research

The whole procurement philosophy in the UK must change to a more collaborative approach ensuring the design of buildings is right for the future climate, with a committed subcontractor design team involved earlier and better management of the programme to eliminate risk. Trust between parties, behavioural change and ***responsible customership*** is needed to ensure that the construction industry would be able to deliver buildings safely and efficiently in the future. The wider implications of the changes needed to how buildings are procured could be considerable, particularly in the approach to contractual terms with regard to delay.

Further research is needed in a number of areas to prepare the construction sector and reduce risks. Tools for project planners and programmers based on statistical projections in the longer term are needed to help to determine what is considered exceptional and adverse weather and how often to expect it. Similar tools for degree days, wind speed

and rainfall intensity frequency and peak conditions are needed to support development of design standards, and review of structural and building design regulations. This will help to make building and services design more appropriate for future climate.

More analysis of the trends towards use of renewable and lower carbon materials such structural timber and annual field crops such as hemp and straw and how sensitive these products might be to climatic change and weather events in their production yield, cost volatility and competing demand from other sectors. The same products are increasingly used as fuel sources and the longer term impact of this may be significant to the ability of buildings to perform in the longer term.

Off-site manufacture can dramatically reduce environmental impact on construction sites by reducing programme and waste, and it is expected that it may also help to reduce weather and climate risks on site such as water scarcity, working in hot or windy conditions. Understanding how vulnerability can be mitigated in delivering, lifting and positioning large prefabricated units and protecting stocks off site should be more fully investigated.

For Contractors, reaction to climate adaptation, resilience and risk management must be appropriate, and finding the correct balance is a sustainability issue in itself to ensure safe, responsible and economically viable construction processes are maintained for the benefit of clients and occupiers throughout the course of this century. There will be a point when adaptation and resilience is not just a good idea to protect business from risk, to being an absolute necessity to remain in business.

6 Acknowledgments

Simons would like to thank participants of the subcontractor workshop and Guy Battle of Deloitte who assisted with presenting climate adaptation research from UKCIP.

Achieving compliance with level 3 of the Code for Sustainable Homes for speculative housing developers in Wales

Sarah Bailey and Paul Ryall

Faculty of Advanced Technology, University of Glamorgan, Pontypridd, CF 37 1DL ,
United Kingdom

Email: pvryall1@glam.ac.uk

Abstract:

The aim of this research was to investigate the cost of achieving compliance with the requirements of the Welsh Assembly Government's Planning Policy Wales framework in relation to achieving specified levels of the Code for Sustainable Homes to gain planning permission for new housing developments in Wales. The UK Government and the Welsh Assembly Government have recognised the urgent need to reduce carbon emissions, a significant proportion of which are produced from the construction and occupation of new homes. Governmental aspirations are to achieve zero carbon homes by 2016, which if achieved will herald a revolutionary change to the methods of building and powering British homes. The Welsh Assembly Government has passionately adopted these aspirations and enshrined them in new regulations for building sustainably in their Planning Policy Wales framework. These new requirements are articulated to achievement of levels of performance standards enumerated in the Code for Sustainable Homes. The research involved the analysis of both qualitative and quantitative data which identified potential methods of achieving cost effective compliance with the Code for volume house builders in the Welsh market. This involved the analysis on a cost per percentage point basis of the credits required to achieve different levels on the Code. Variables that will affect these computations were also examined. Data was gathered from an analytical case study involving an existing house design template used to compare existing specifications with the extra over costs involved in achieving levels on the Code and from interviews with relevant stakeholders in this process. The authors finally drew conclusions on the significant consequences of the new requirements of the Welsh Assembly Government's planning framework and made recommendations for a volume house builder to implement in their operations in Wales to promote achievement of the relevant standards currently and in the future.

Keywords:

building procurement, Code for Sustainable Homes, house building in Wales, sustainable building.

1 Introduction

The introduction of The Code for Sustainable Homes (the Code) originated from a statement in 2007 by Yvette Cooper MP, former Minister for Housing and Planning (Video: 2007):

“We have to cut carbon emissions from homes. We know that about a third of the homes we will be living in by 2050 have not yet been built and that is why it is so important that we improve the technology, cut the carbon emissions from the new homes. And we want a star rating, a code for sustainable homes to tell people just how well the new homes are doing.”

This statement was further expanded upon by the Minister(2007, Pg.6) pledging that by 2016 all new homes should be zero carbon and that to achieve this nothing less than a revolution in the way we heat, light and power our homes is required as it is estimated that a quarter of all CO² emissions come from our homes.

This need for a reduction in CO² emissions has been recognised and an attempt made to address it by the Welsh Assembly Government through its Ministerial Interim Planning Policy Statement (MIPPS): Planning for Sustainable Buildings (01/09) (2009b, Pg.3):

“To move towards more sustainable and zero carbon buildings in Wales, the Assembly Government expects that the following standards will be met:-

Applications for 5 or more dwellings received on or after 1st September 2009 to meet Code for Sustainable Homes Level 3 and obtain 6 credits under issue Ene1 - Dwelling Emission Rate”

Applications for 1 or more dwellings received on or after 1 September 2010 to meet Code for Sustainable Homes Level 3 and obtain 6 credits under issue Ene1 - Dwelling Emission Rate.

The authors’ aim in the research was to establish the cost of achieving compliance with Level 3 of the Code for Persimmon Homes East Wales (PHEW). Persimmon Homes East Wales is a subsidiary company of Persimmon Plc and builds approximately 450 homes per annum in South East Wales.

To achieve the aim and to enable recommendations to be put forward to PHEW on how they were to approach their first planning application under the MIPPS (01/09) regime the research was concentrated on the following aspects:

An examination of the Code for Sustainable Homes

Requirements in Wales in regard to compliance with the Code

A Case Study which examined the extra over cost of achieving level 3 of the Code on the PHEW Cothi 3 Bedroom 814 Ft² House Type:

Identification of the most cost effective method to achieve level 3 and 31% Improvement on current building regulations for Ene1

This research was conducted and in part written prior to the commencement of the Consultation on the Code for Sustainable Homes and the Energy Efficiency standard for Zero Carbon Homes. It therefore does not take into considerations any of the issues raised as part of the consultation and issue of the latest version of the Code. These issues have been considered and incorporated into further research on this topic and will be the subject of another paper.

2 Literature Review –The Code for Sustainable Homes

The Code for Sustainable Homes (the Code) forms part of the Government's aim to improve the sustainability and environmental/energy efficiency of new homes, in particular concentrating on reducing carbon dioxide (CO²) emissions and achieving its overall target for all new homes to be zero carbon by 2016.

2.1 Categories

The Code comprises of nine categories of environmental sustainability, each category has a varying number of credits available, each credit has a percentage weighting resulting in a total percentage for each category. Table 1 below extracted from The Code for Sustainable Homes Simply Explained (Gaze et al, 2009, p.7) illustrates this.

Table 1 – Categories of The Code

Category		Issue	Number of Credits	Weighting Factor (%)
1	Energy & CO ² Emissions	ENE1: DER (m)	29	36.4
		ENE2: Building Fabric		
		ENE3: Internal Lighting		
		ENE4: Drying Space		
		ENE5: Energy-labelled white goods		
		ENE6: External Lighting		
		ENE7: LZC Technologies		
		ENE8: Cycle Storage		
		ENE9: Home Office		
2	Water	WAT1: Indoor Water Use (m)	6	9.0
		WAT2: External Water Use		
3	Materials	MAT1: Environmental impact of materials (m)	24	7.2
		MAT2: Responsible sourcing of materials-basic building elements		
		MAT3: Responsible sourcing of materials-finishing elements		
4	Surface Water Run-Off	SUR1: Management of surface water runoff from developments (m)	4	2.2
		SUR2: Flood Risk		
5	Waste	WAS1: Storage of non-recyclable waste and recyclable household waste (m)	7	6.4
		WAS2: Construction site waste management (m)		
		WAS3: Composting		
6	Pollution	POL1: Global warming potential of insulants	4	2.8
		POL2: No _x emissions		
7	Health & Well Being	HEA1: Daylighting	12	14.0
		HEA2: Sound Insulation		
		HEA3: Private Space		
		HEA4: Lifetime Homes (Level 6 Only)		
8	Management	MAN1: Home User Guide	9	10.0
		MAN2: Considerate Constructors Scheme		
		MAN3: Construction Site Impacts		
		MAN4: Security		
9	Ecology	ECO1: Ecological Value of Site	9	12.0
		ECO2: Ecological enhancement		
		ECO3: Protection of ecological features		

	ECO4: Change in ecological value of site	
	ECO5: Building Footprint	

(m) - Mandatory Element

2.2 Levels of the Code

The Code has six levels each with a required amount of percentage points, from level one at 36 points through to level six at 90 points. This is demonstrated in Table 2.

Table 2 – Code Levels

Total percentage points score (equal to or greater than)	Code Levels
36 Points	Level 1 (*)
48 Points	Level 2 (**)
57 Points	Level 3 (***)
68 Points	Level 4 (****)
84 Points	Level 5 (*****)
90 Points	Level 6 (*****)

(Source : The Code for Sustainable Homes, Gaze et al .,2009, p17)

Within each code level there are a number of mandatory minimum requirements: ENE1, WAT1, MAT1, SUR1, WAS1, WAS2 and HEA4 which becomes mandatory in 2013 for Code level 3 and above.

2.3 Assessment under the Code

The assessment is a two stage process: design stage assessment and post construction review. The design stage assessment is based on drawings, specifications and design commitments, the results of which are shown in an interim certificate of compliance. The post construction review is to prove that the design assessment goals have been met. If any changes in the design have been made they should be identified and re-assessed accordingly. Eagles et al, (2008, p.13), emphasize that all evidence of compliance should be recorded during the construction process to save both time and money later.

An appropriately qualified Code Assessor will carry out both the design stage assessment and post construction review and should ideally be appointed at the planning stage of the development. Eagles et al (2008, p.12) argue that the Code Assessor is a valuable member of the construction team who is not only responsible for completing the Code assessment, but can also assist on which credits should be aimed for and how they can be best achieved. To confirm compliance two certificates are issued by the

Code Assessor: an interim certificate at the design stage and a final certificate at the post construction stage. Flow charts explaining both the scoring and assessment system are demonstrated fully in The Code for Sustainable Homes (Anon, 2008b, p.18)

2.4 Mandatory Requirements

The Code focuses on saving energy and water and therefore categories ENE1 and WAT1 are considered the most critical to sustainability and have mandatory requirements across all Code levels. There are currently four additional areas of mandatory requirement: MAT1, SUR1, WAS1 and WAS2.

2.4.1 ENE1 – Dwelling Emission Rate

This category relates to the Dwelling Emission Rate (DER) measured as a percentage improvement in CO² emissions compared to current building regulations and Target Emission Rate (TER).

To meet Code level three the mandatory requirement is set at 25% improvement in DER over TER which would earn five credits, however in Wales the requirement is set at 31% improvement which would earn 6 credits.

2.4.2 WAT1 – Indoor Water Use

The focus of this section is on reducing internal water use which is measured through a maximum usage in litres per person per day. For Code level three the maximum consumption is 105 litres per person per day, earning 4.5 credits.

2.4.3 MAT1 – Environment Impact of Materials

This element encourages the use of materials with lower environmental impact over their lifecycle. There are five constructional components examined: roof, external walls, internal walls, floor and windows. To meet the mandatory requirement for all Code levels three of the five elements must be BRE Green Guide rated D or above. Credits are awarded from 0.25 – 3 per component depending on its rating: 3 credits are awarded for an A+ rating down to 0.25 of a credit for a D rating. A maximum of 15 credits can be achieved.

2.4.4 SUR1 – Management of Surface Water Run Off

Probably the most challenging section of the Code, at one of the conference proceedings attended by the authors the Sustainable Construction Manager for BRE (King, 2009) stated that he firmly believed it is actually impossible to achieve compliance on some developments. In essence the peak run off rate into water courses for the developed site must not exceed the pre-developed site. No credits are awarded for achieving the mandatory requirement however 2 credits can be achieved for improvements through the use of Sustainable Drainage Systems (SUDS). For the purpose of this research it has been assumed that the mandatory requirement will be achieved.

2.4.5 WAS1 – Storage of Waste

Adequate internal and external space should be provided for waste. This mandatory requirement can be met either through local authority provisions or calculated using BS5906: 2005. It should be noted that the area provided should be accessible to all

including wheelchair users. No credits are awarded for meeting the mandatory requirements.

A total of 4 credits can be achieved through the provision of the following facilities:

Three internal storage bins located in an adequate storage space each of 7 litres minimum capacity

All internal storage must be a minimum of 30 litres combined capacity.

At least three external bins again located in an adequate storage area.

No bin is to be smaller than 40 litres with a total storage capacity of 180 litres.

2.4.6 WAS2 – Site Waste Management

For developments over £200,000 it is a mandatory requirement for waste on site to be managed effectively through a site waste management plan. No credits are awarded for meeting mandatory requirements. However, if the site waste management plan details information regarding procedures and best practice for waste minimisation and diverting waste from landfill through recycling, 2 credits can be achieved.

2.5 Stand Alone Credits

Although building to level three of the Code is more technically demanding there are some simple, relatively low cost changes that can be implemented to achieve credits which have little or no impact on the other areas and can provide 8% of the total points available (Gaze et al, 2009, p.14).

2.5.1 ENE4 – Drying Space

The provision of an internal or external drying space for clothes provides 1 credit or 1.25% points.

2.5.2 ENE5 – Energy Labelled White Goods

The developer can either install energy efficient white goods as follows to obtain the full 2 credits or 2.51% points:

Fridge Freezer – A+

Washing Machine – A

Dishwasher – A

Tumble Dryer – B

Gaze et al (2009, p.15) found that if a developer chooses to install appliances in a property the premium for the installation of energy efficient appliances is small. However, if the developer does not offer appliances, by providing information on the EU energy efficiency labelling scheme they will gain 1 credit or 1.25% points.

2.5.3 WAS3 - Composting

For houses a simple composting bin provided in the rear garden gains the full credit. For apartments it is not as simple; however with more and more local authorities providing composting services the single credit or 0.91% points can be obtained through this.

2.5.4 MAN1 – Home User Guide

Most of the information required for a Home User Guide will have to be made available to the Assessor so collating it into a single document for the end user is straight forward. The other information required such as that relating to the local area is readily available and providing this information to the end user will result in three credits or 3.33% points awarded.

2.6 Code Level 3 Requirements in Wales

Planning policy of the Welsh Assembly Government is encapsulated in the strategic document Planning Policy Wales, which comprises sections titled Ministerial Interim Planning Policy Statements (MIPPS), each of which deal with different aspects of policy. MIPPS 01/09 articulates the Assembly's requirements for sustainable building within the Principality. Technical Advice Notes (TAN) provide guidance on how to achieve the requirements of the MIPPS.

MIPPS (01/09) dictates that compliance with level three of the Code only applies to outline and full planning applications submitted after 1st September 2009. As part of the MIPPS (01/09) (2009b, p.3) a 31% improvement in DER on TER is required as opposed to a 25% improvement for properties built in England.

In an interview with the Managing Director of PHEW, the authors confirmed that the company are in a strong position in terms of their land bank, with planning permission for the properties required to fulfil over 18 months budget already secured prior to the September 2009 deadline imposed by the Welsh Assembly Government (WAG). The company chose to obtain outline planning permission on as many strategic parcels of land as possible prior to September 2009 in an attempt to mitigate the extra costs of the Code's requirements and also to allow as long as possible to get compliance 'right' both in terms of sustainability and cost.

2.6.1 Zero Carbon

Consideration needs also to be given to the desire of the Welsh Assembly Government (WAG) to achieve 'zero carbon' emissions from new buildings by 2011 (WAG, 2010). Although at a conference Francois Samuel of WAG (2009) pointed out that 2011 is prior to the devolution of the Building Regulations which is set to be completed by 31st December 2011, therefore it was felt that the reality would be that the maximum stepped changes practical would take place in the immediate future and post 2013 would be the earliest opportunity to achieve 'zero carbon' in Wales.

This was confirmed at a House Builders Federation(HBF) forum by Jane Davidson (2010), WAG Minister for Environment, Sustainability and Housing, that 'zero carbon' for all new buildings in 2011 was merely an aspiration for WAG and this target is now being revised and is likely to be 2013 before this is achieved

It should be noted that prior to working towards achieving zero carbon a firm definition is required for the industry. At the Wales Low/Zero Carbon Hub Workshop the Minister discussed the definition comprising of a 70% reduction in DER over TER with 30% allowable solutions being the way forward for 'zero carbon' (Davidson, 2009). At the same conference the Head of Housing for the HBF confirmed the need for a clear definition for the allowable solutions in order for 'zero carbon' to be achieved (Pannell, 2009).

An example to illustrate the confusion surrounding allowable solutions is that of The Miller Zero Project by Miller Homes. In Basingstoke properties have been built to each level of the Code and to achieve Code level 6 a wood chip biomass boiler was used to provide under floor space heating and hot water. The allowable solution used was that the carbon omitted from the wood chips when burnt had previously been absorbed (Mann, 2009). It can be legitimately argued as to whether this is really achieving zero carbon and begs the question as to whether this is truly a sustainable approach as the analogy could be drawn for hydrocarbon fossil fuels albeit that the carbon dioxide absorption occurred in a different epoch.

2.6.2 Energy Hierarchy

The energy hierarchy, illustrated in Section 3.2 of the Technical Advice Note (Tan) 22(Anon,2009a, p.12), states that the use of renewable energy sources should be avoided until all the other principles of the energy hierarchy

The Sustainable Construction Manager for BRE (King, 2009) confirmed in a conversation with the authors that the key to achieving compliance with level three of the Code was to concentrate on improving the fabric of the building; this will result in a decrease in energy demand and an increase in energy efficiency.

King (2009) substantiated his claim in his presentation to the Wales Low/Zero Carbon Hub Workshop by stating that from the pilot schemes run to date in Wales by Registered Social Landlords (RSL) it has been proven that the u-values of the fabric should be taken to:

0.21 - walls

0.13 - floors and roof

1.20 - windows

Air tightness of 3

Attempting improvements beyond these values provides only a small reduction in CO² compared to the uplift in costs.

3 Research Methodology

The methodology involved an initial literature review and attendance at two specialist conferences which allowed individual discussions with one of the seminal authorities on

the Code and subsequent interviews with senior professionals involved in housing procurement Wales. This initial investigation identified the importance of design and compliance requirements and the principles necessary to satisfy these. This then facilitated the case study cost analysis performed on a existing PHEW house template and which compared the existing specification with amendments to this to achieve compliance with level 3 of the Code in the most cost effective manner. This allowed the articulation of a specification to achieve level 3 and conclusions to be drawn and recommendations for PHEW, and more broadly for the sector in Wales, to be made in regard to future planning and design processes to satisfy the requirements of MIPPS 01/09. The research also identified potential effects on land values and consequently corporate profitability for developers operating in Wales.

4 Findings and discussion

4.1 The case study

Using the PHEW Cothi 814 Ft² house type, a typical 3 bedroom end terrace home as a case study, an analysis of the current specification against the Code has been undertaken. The Cothi type is a traditional 3 bedroom 2 storey home, either terraced or semi-detached comprising of an entrance hall with downstairs cloakroom. The kitchen is to the front of the property with a spacious lounge /dining room to the rear with French doors leading to the rear garden. The first floor hosts the master bedroom with en-suite, two additional bedrooms and family bathroom.

4.2 Assumptions

The baseline specification for a Cothi to meet current building regulations is shown in Table 3.

PHEW stipulated that for the purposes of this research traditional external elevations should be maintained where possible and that traditional masonry construction to be preferred over timber frame.

SAP calculations were carried out using BRE Approved 2005 SAP software meeting Part L 1A, 2006 requirements.

4.3 Assessment of existing house type

Initially an appraisal was made of the current specification of the Cothi house type, breaking it down into the various Code requirements; this demonstrated that the current specification only achieved 18.38% against a requirement of 57% to achieve compliance with level three of the Code. This assessment is shown in Table 3.

4.4 Level Three Analysis

In order to achieve the remaining 38.62% the following steps were taken:

Firstly the mandatory elements of the Code, as examined previously, were considered. These credits, plus the additional credits obtained as a by product of these mandatory requirements, namely ENE2 and POL1, resulted in an additional 15 credits being obtained and an additional 16.13% overall. These were achieved at an extra over cost of £3,855.

The total percentage points were then 34.52%, leaving a further 22.48% required to achieve level three.

To achieve the remaining 22.48% an analysis on a cost per percentage point basis was undertaken, whilst considering the perceived value of the eco friendly options.

O'Donnell (2010) confirmed in a conversation with the authors that it is deemed essential as part of the planning process to carefully consider the management and ecology categories of the Code. These categories amount to a total of 18 credits or 22%. With current house type designs 14 credits or 16.65% are achievable at a cost of circa £398.00, argued by O'Donnell (2010) as a very cost effective way of obtaining 16.65%. Compared to an extra over cost of £3,855 for the 16.13% for the mandatory element £398.00 does appear a cost effective way of obtaining a significant number of credits.

At this point the total credits totalled 48.96%, leaving only 8.04% to achieve compliance.

This phase of the assessment required further careful deliberation and was found to involve a degree of subjectivity. The aim of this research however, was to find the most cost effective way of achieving compliance therefore the elements included in the assessment shown in Table 4 utilise the lowest cost per credit items.

For example, previously it was illustrated that a composting bin was a easy way of obtaining 0.91%, however at a cost of £85.00 per bin (Sugar, 2010) this option was dismissed. Instead an external water butt was chosen at a cost of £95.00 (Sugar, 2010) achieving 1.50%.

Similarly superficially a cycle store (in ENE8) would appear to be an 'easy' method of obtaining 2.52%, however, at a cost of circa £420.00 (Sugar, 2010) for the provision of a shed and base this option was also rejected. Instead a combination of 75% low energy lighting, external lighting, a drying space for clothes and information conforming to EU guidelines relating to appliances was chosen at a cost of £317.00 (Sugar, 2010) and 7.53%.

It should also be noted that several categories were simply unobtainable due to the current design of the Cothi and many of the other PHEW house types. These are ENE9, HEA1, HEA4 and ECO5.

The full evaluation is shown in Table 4.

4.5 Published Cost Analyses comparison

Various figures have been published regarding the cost of achieving level three of the Code:

Official reports from the government suggest figures between £4,947 and £5,801 (Anon, 2008a, p.32).

In a more recent report by Gentoo figures between £3,945 and £3,978 are suggested (Thompson & Morrison, 2009, p.45).

Taylor Wimpey (2008, p.2) believe that their costs will be 10%-20% higher than the official government figure and are suggesting an extra over cost of £6,246 for a typical three bedroom mid terraced home.

A more rounded figure of £5,000 per plot has been given as a guide in conference proceedings by the Wales Low/Zero Carbon Hub (Pannell, 2009)

This research has enumerated an extra over cost of £4,985, based on prices of materials available to PHEW. This figure is in line with the other published costs, however it should be noted that this figure achieves 31% improvement in DER on TER whereas the other reports are based on a 25% improvement to comply with English legislation. This may then suggest that industry estimates of the extra over cost of achieving level 3 maybe pessimistically high given the cost significance of ENE1 illustrated in Table 4.

Table 3 – Current Specification

Code for Sustainable Homes		Current Specification		
Code	Section	Max Credits	Credits	Comments
Category 1 - Energy & CO₂ Emissions				
ENE1	Dwelling Emission Rate	15	0	Only 2.4% over DER
ENE2	Building Fabric	2	0	1.34 Heat Loss Parameter
ENE3	Internal Lighting	2	0	Only 4 from 11 fittings are low energy = 36% Min 40% Req.

ECO2	Ecological Enhancement	1	1	Fulfill recommendations of report	£25.00
ECO3	Protection of Ecological Features	1	1	Default as per ECO1	£0.00
ECO4	Change in Ecological Value	4	2	Assume change is neutral	£0.00
ECO5	Building Foot Print	2	0	By product of design and therefore non compliance	£0.00
Total Credits		9	5	Total E/O Cost for Cat 9	£75.00
% Points (Weighting of 1.33)		12.00%	6.67%		
TOTAL CREDITS		100.00%	58.00%	TOTAL E/O COST FROM STD SPEC £4,665.00	
REQUIREMENTS FOR LEVEL 3		57.00%	57.00%		

5 Conclusions and Further Research

To conclude the Code has significant consequences for the speculative house builder in Wales and the authors believe the following:

Cost effective proposals to achieve level 3 compliance for an existing house template has been presented in Table 4.

The extra over cost of achieving level 3 of the Code may have been over-estimated if the authors' case study analysis is compared with other studies published in the literature.

At the time of the research build cost above ground for the Cothi type house was approximately £52 per square foot (no garage included in this figure) with a total cost of approximately £43,000. Therefore the £4,600 extra over cost to achieve level 3 of the Code is circa 11% of above ground build cost.

In practical terms, it is evident from the research undertaken that a solid understanding of the Code and its requirements are essential to any developer and appointing a code assessor at the earliest possible stage is important in the process to achieve success.

The WAG requirement under MIPPS (01/09) for a 31% improvement in DER on TER requires significant improvements to be made in the fabric of the building and this is inevitably where the majority of the extra over cost lies. In the case study used, approximately 80% of the total extra over cost was to achieve compliance with ENE1 for only 6 credits or 8.79%. It is therefore essential that during the initial design stage of a development the energy hierarchy is exhausted and anyone working on the project should be mindful of the required u-values and the diminishing returns that apply.

It was found that the most debatable and arduous element of achieving cost effective compliance with the Code arises after fulfilling the mandatory elements, and it was established that a comparative analysis on a cost per percentage point basis was the best way forward. It is important to note that what may appear superficially as an easy option to gain credits may not necessarily be the most cost effective approach.

The published estimates of extra over costs for building to level 3 of the Code are wide ranging. The authors believe that this can be significantly affected by material costs and buying power which would indeed vary from business to business. Thus it can be seen that the supply chain and future technological developments will play a critical role especially when legislative performance levels are raised.

6 Recommendations

In order for Persimmon Homes East Wales, and other developers, to cost effectively meet level three of the Code the following recommendations are made in addition to the proposals outlined in Table 4 above:

Organise appropriate training courses for key members of staff – internal staff need parity of knowledge with externally appointed Code assessors.

Share knowledge. Stakeholders should continue working with the HBF on workshops such as the Wales Low/Zero Carbon Hub Workshop to discuss the issues surrounding the Code in an open forum.

Secure best value from the supply chain. New technology will be critical to success in the future and companies should invest time on securing group deals for these new products to ensure the best price possible is negotiated which will result in lower extra over costs than illustrated in the case study. This will become ever more crucial as higher levels on the Code become the legislative requirement in Wales as the country moves closer towards the aspiration of zero carbon development.

Follow the steps taken by the authors and carry out a cost per percentage point analysis once the best possible prices for new technologies have been agreed with potential suppliers and try to improve on the £4,665 extra over cost obtained from the case study.

Recognise and remember that the obvious choices for ‘easy’ credits are not necessarily the cheapest and possibly environmentally most effective. A small amount of time spent on cost analysis at the outset may result in savings in the long run.

7 Acknowledgements

The authors would like to acknowledge the substantive support provide by Persimmon Homes East Wales and especially Mr Andy Baker-Edwards, Technical Director for Persimmon Homes East Wales and Mr Carl Sugar, Commercial Manager for Persimmon Homes East Wales. Also thanks to Mr Kevin O’Donnell of Building Energy Performance Ltd.

A Project Alliance Approach for the Procurement of Indigenous Social Housing in Australia

Marcus Jefferies¹, Adam Schubert¹ and Ramsey Awad¹

¹School of the Architecture and Built Environment,
University of Newcastle, Callaghan, NSW 2308, Australia

Email: marcus.jefferies@newcastle.edu.au

Abstract:

The standard of living conditions for indigenous Australians in remote areas of the Northern Territory (NT) is widely acknowledged as being below standards the remainder of the population is accustomed to. Project delivery programs have failed to address issues of overcrowding, poor living conditions and insufficient infrastructure that have proved to be a primary contributor to indigenous disadvantage leading to poor health, reduced life expectancy, and social, economic and cultural. Delivery methods for indigenous social housing and infrastructure is in need of reform to overcome the mounting problems and to address continuing disadvantage of indigenous communities. A current Government initiative is the Strategic Indigenous Housing and Infrastructure Program (SIHIP) which is using an Alliance approach to deliver the planning, design and construction stages for social housing. Project Alliancing is a form of relational contracting that provides value for money, fosters trust, manages team goals, attracts multi-disciplinary expertise and encourages innovation in order to develop the best possible solutions for project delivery. Alliancing is characterised by project arrangements which ensure that risk is shared across all participants under a pain/gain-share system to overcome previous problems with traditional contractual approaches which have been adversarial and inefficient. Through a case study approach, this paper analyses the SIHIP Project Alliance framework and focuses on specific outcomes of the Alliance partners. The SIHIP was particularly successful in terms of redefining program management principles, integrating community consultation and cultural considerations and delivering sustainable housing projects for indigenous Australians.

Keywords:

Australia, Government projects, indigenous social housing, project alliancing, sustainable procurement

1 Introduction

The management of construction projects and associated research is grounded in achieving successful production of a project throughout the entire life cycle of the construction process. Effective management and use of resources throughout this entire holistic process is the key to successfully producing a product in the built environment (Harris et al, 2006). It is the procurement approach that provides a framework for all the aspects of construction to be holistically brought together to produce a successful

product Walker (2008). Development of procurement strategies can effectively govern the success, efficiency and sustainability of a construction project. It is this that governs the aim of this paper, which sets out to identify issues with the problem of providing adequate and appropriate housing for remote indigenous communities. This has been identified as a serious problem throughout Australian history by the likes of Read (2000), who covers a history of the research into the social, political and cultural problem; and both Pholeros (1993) and Memmott (1989), who further describe problems with Indigenous Housing (IH), particularly those with the construction and provision of houses in the remote Northern Territory (NT) of Australia.

Recent innovations in procurement have led to the development of contracting frameworks that aim to address the increasing nature of change and complexity of the construction industry. Formed around the characteristics of developing relationships, sharing risk and collaborative and innovative development of solutions, Project Alliancing is a contracting system which embraces change, adapts to obstacles and enables participants to work together to achieve increased project performance and improve the key outcomes of time cost and quality. It is the choice of implementing the Project Alliancing framework for the delivery of remote IH in the Strategic Indigenous Housing and Infrastructure Program (SIHIP) that forms the basis of this paper.

Subsequently, the aim of this paper is to:

“Evaluate the SIHIP Project Alliancing procurement model in delivering culturally, economically and socially successful Indigenous Housing outcomes.”

The significance of the problems associated with indigenous housing is pronounced and evidence is wide spread. With grossly overcrowded houses, poor performance of utilities, no maintenance and deteriorated, unsafe buildings (Pholeros 1993), (ABS 2006), (FaHCSIA, Australian Dept. of Families 2007), Indigenous Australians in the remote areas of NT have the lowest socio-economic profile of all Australians. Procurement in construction is an evolving process that provides a framework for the successful and effective delivery of a construction project over its lifecycle (Walker, 2008). Long and Memmott (2007) identify Indigenous housing as having to incorporate all aspects of production, management, maintenance and occupation of indigenous living environments. In addition the NT governments' Department of Local Government and Housing has identified problems with current IH and their solution involves the provision of adequate housing and services to remote indigenous communities.

The development of the SIHIP saw the choice of Project Alliancing as the most effective contracting method for successful delivery of IH (FaHCSIA, Australian Dept. of Families 2009). Therefore, drawing on issues of remote IH and the successful attributes of Project Alliancing procurement strategies, this paper will evaluate the success of the SIHIP in solving problems that plague the NT indigenous communities.

2 Literature Review

2.1 History of Indigenous Housing

The management and quality of housing and the built environment have always been a primary determinate of indigenous disadvantage, especially in remote communities. The

1970s saw the first official definition and identification of issues revolving around housing and infrastructure and how it served as a major element of concern for the living conditions, health and overall social wellbeing of the Australian indigenous people. Rowley (1971) described housing or the level of dwellings during that era, as an issue decaying the standard of living of many remote aboriginal communities. The poor standards of living including poverty, lack of education, violence and health issues became attributed to the primary issue of insufficient and inappropriate housing. Heppell (1979) drew these conclusions along with the need for improved government policy aiming at the immediate need and the development of long term solutions to problems with Indigenous housing in remote Australia.

Memmott (1990), Saunders (1990) both gave developed insight into housing policy for indigenous Australians and identified areas of concern. They covered the need for both state and federal policies to understand the specific need for positive development of housing. This related not only to provision, but the specific design, construction and delivery of the projects that would be appropriate to the needs of remote Indigenous communities, especially in regard to culture, living standards and remote sustainability. The situation in recent years has continued to be problematic with issues of overcrowding, low quality construction, inefficient planning, poor community infrastructure and lack of basic services and utilities (ABS 2002). Reviews of government programs also confirmed some problems not only with the housing itself but also the method of delivery and focused more specifically on poor construction, maintenance and management of housing, fragmented and failing housing organisations and ill allocation of funding (FaHCSIA, Australian Dept of Families 2007).

The current SIHIP is utilising almost A\$700M funding and is the largest IH program undertaken by the Australian and NT governments (FaHCSIA, Australian Dept. of Families 2009). The primary aims reflect those of similar policies and past programs, with additional objectives to improve remote indigenous built environments through the construction, rebuild and refurbishment of houses

2.2 Procurement of Indigenous Housing

Pholeros (1993) identified the need for a system of procurement involving industry, government and community partnership. In his contribution to the benchmarking framework in service delivery (Council for Aboriginal Reconciliation: Benchmarking Workshop, 1997) he stated that the need has been defined and it is time to develop solutions and begin work to improve the day to day living environment. There was also definition that the policies must match the practical work, which is difficult with the complexity and layers on many of the current and previous policy. From his work in the communities he identified the problems attributed to poor design, construction standards and overall management of the construction process. There was even reference to developing a specific section of the Building Code of Australia (BCA) for indigenous and remote housing and infrastructure (AIHW, 2005). It was also identified that for Government programs to achieve their objectives the process of implementation and construction must be managed and organised better (Barker, 2003).

2.3 Project Alliancing

Construction projects are by nature dynamic, ever changing and inherent with risks. These levels of risk and the growing size and complexity of projects has attributed to

the adversarial and fragmented nature of the construction industry (Noble, 2007). Project Alliancing aims at effectively managing risks and encouraging more collaborative, relational and contractual partnerships between stakeholders to better achieve the objectives and improve overall project performance. Project Alliancing utilises the principles of sharing risks and benefits in to develop relationships and integrate the project team to maximise project performance (Walker, 2008).

According to the Victoria Governments 'Project Alliancing Practitioners Guide' (Dept. of Treasury and Finance, 2006), an Alliance is "a commercial/legal framework between a department, agency or government-business enterprise as 'owner-participant' and one or more private sector parties as 'service provider' or 'non-owner participants' for delivering one or more capital works projects. The system demonstrates characteristics of a partnership in that there is a collective sharing of almost all project risks and benefits, a no blame/no disputes agreement, with an integrated project team selected on best placed entities and a principle based strategic management process. In partnership, each entity provides their services on a net cost basis, and upon completion of the project the parties share in the profits and or losses respectively.

Traditional forms of contract such as construct only or combined design and construct systems consist of project risks being allocated to the party believed best placed to mitigate and manage the risk. The terms and conditions of traditional contracts aim at predicting all possible outcomes and assign liability and when changes and alterations occur, the result often ending in dispute. Project Alliancing is built on partnering to embrace collaboration, change and innovation in project delivery (Sakal 2005). Another prime characteristic of an Alliance is the early involvement of contractors and other stakeholders to encourage innovation, collaboration and allowing the design, construction and use of the occupation of the project to be integrated (Scheublin, 2001).

Alliance systems have been used on numerous capital works and infrastructure projects in the Australian public sector. To take advantage of Alliancing in the public sector, some Australian State Governments have developed a set of guidelines detailing the processes and framework for using Alliances to deliver major capital works. Australian projects utilising Alliances include Sydney water infrastructure works, Dept of Defence projects, and major road and civil works from both local and state governments (Dept of Treasury & Finance, 2006). However, the use of Project Alliances to deliver building projects across the public and private sector has been limited, the SIHIP is another of the first major building projects to utilise this system, and the project offers its own unique risks and challenges. The following table lists the benefits and risks associated with using an Alliance based contracting system such as Project Alliancing.

Table 2: Benefits and risks of project alliancing (Adapted from Sakal, 2005; Victorian Government, 2006; and Walker 2008)

BENEFITS	RISKS
'Best for Project' not 'Best for Individual' commercial focus	Participants are responsible for larger range of risks & liable for the performance of other participants
Improved ability to manage risk, uncertainty and change through shared responsibility and resources	The absence of competitive tendering and pricing may lead to questioning the value for money
Early involvement of contractors and consultants	Larger levels of involvement by senior participants
Reduced need for contractual administration, reduced disputes, claims and litigation	Resource intensive
Encourages innovation and high standard of work	No maximum or capped pricing for clients/owners
Collaboration provides development opportunities for client and alliance teams	Risking profit and overheads for non owner participants
Increased accountability and transparency in costs. More robust budgeting and value for money	High costs of tendering
Project objectives aligned and achieved efficiently through incentives for Non owner participants	Requires full commitment and may reduce the ability to perform normal business activity.
Costs and budgets are developed over the course of the project to reduce overall prices and get vfm	Legal recourse against participants is limited to wilful default or acts of insolvency

3 Research Methodology

The data collected for this paper involved a number of levels of inquiry. Primarily, the research focused on published literature and secondary data. This allowed the researchers to understand the themes based entirely on the information at hand without opinion or subjectivity (Knight 2008). The preliminary stages of research analysed current and historical literature to gain an understanding of the issue of remote indigenous housing, and identified the need for a procurement approach specific to this problem. The issues or principles of IH established via a review of literature were identified as both problems and contributors to successful outcomes. Subsequently developed into criteria, the principles were used to evaluate a case study of the Project Alliancing procurement system developed for the SIHIP in the Northern Territory of Australia. The evaluation was based on the performance review documentation and published statistical data representing the outcomes of the SIHIP.

4 Findings and Discussion: The Strategic Indigenous Housing and Infrastructure Program (SIHIP)

The Strategic Indigenous Housing and Infrastructure Program (SIHIP) is a current initiative of the Australian and NT governments aimed at improving housing outcomes for indigenous Australians in rural, remote and very remote areas of the NT. The program is the largest of its kind and SIHIP will construct new houses, rebuild and refurbish existing houses in over 70 remote regions in the NT. Delivered using Alliance contracting the SIHIP was developed to achieve the objectives of national IH policy and address the issues of previous projects through timely and cost-efficient delivery.

4.1 Development of SIHIP

The program, as a part of the reform agenda depicted in the National Partnership Agreement on Remote Indigenous Housing (NPA RIH), was announced in April 2008. The SIHIP replaced the previous arrangements of the Aboriginal Rental Housing and Community Housing and Infrastructure Programs, following the trend of federal and state funding and state controlled delivery of the program. It was the agreement between the federal and NT governments which initiated the establishment of the SIHIP in response to the recognition that previous housing programs had been unable to achieve the desired outcomes (COAG 2008). The project aimed to address the large shortfall in housing stock, overcrowding, poor living conditions and overall community, social and economical disadvantage to the Indigenous population in remote NT (ABS 2006).

Recognition of the multitude of problems combined with the understanding that previous programs were failing to achieve the desired outcomes prompted a change in program structure and project delivery. As the general delivery method was previously standard one-off, lump-sum contract agreements, the programs failed to achieve value-for-money and the economies of scale that are needed for successful outcomes in a unique project such as this. Presented with a range of business and policy challenges unique to the remote Indigenous regions of the NT, such as cultural and social considerations, history and heritage, environmental and climate restrictions, limited resources and a significant potential scope of works, the government agreed that a alternative procurement approach may be able to achieve the required outcomes (FaHCSIA, Australian Dept. of Families, 2009). A system which provided incentive for quality outcomes, sharing of risk, responsibility and benefits, and greater elements of indigenous employment, training and overall community development would be a significant driver for change to achieve more sustainable improvement.

The SIHIP was initiated in September 2007 (DHLGRS, Dept. of Housing 2010) and aimed to deliver the construction of new housing, refurbishment and upgrading of existing housing, including servicing of sites, improvement of living conditions and communities in the remote areas of the NT, in addition to infrastructure and capital works. Announced in late 2008 the program was initially provided with \$538 million worth of funding from the Australian Government an additional \$100 Million from the NT Administration. The NT Government delivered the program through the Project Alliancing procurement system and would also be responsible for property management, collection of rent and routine maintenance though the public housing framework. The Australian government would provide support throughout the program, oversee the delivery and provide governance and guidance of key decisions and the strategic direction of the program.

4.2 The Project Alliance Approach for SIHIP

It was decided that a Strategic Alliance procurement system would be the most effective approach to achieving the objectives of the program through best practice procurement. The system had the potential to achieve greater economies of scale, better value for money, and grab the attention of innovative and successful international companies with the capacity to partner with smaller local firms capable of integrating and engaging the local community (FaHCSIA, Australian Dept. of Families 2009). Initiated in 2007 the system was based around the Victorian Governments 'Project Alliancing Practitioners Guide'. The procurement approach is based around the following characteristics:

Collective sharing of project risks;

No, fault, no blame and no dispute between alliance participants;

Payment of NOPs for their services under a '3 limb' compensation model:

Reimbursement of NOPs project costs on a 100 percent open book basis;

A fee to cover corporate overheads and normal profit; and

A gainshare/painshare regime where the rewards for good performance and the penalties for poor performance are shared equitably.

Unanimous principle based decision making on all key project issues; and

An integrated project team selection based on best person for each position.

Early involvement of contractors

Specific details of the SIHIP Project Alliance are summarised in Table 2.

Table 3: SIHIP Project Alliance Details

PROCUREMENT SYSTEM	<p>Alliance Contract System:</p> <p>Separated into 3 regional project alliance partners assigned work packages in separate geographical regions. Engaged to collaboratively manage the delivery, design, construction, refurbishment and management/maintenance of the project</p>
GOVERNANCE	<p>NT Government:</p> <p>Contracting entity, responsible for the delivery of the program, management of contracts, organisation of land tenure, capital works and development planning.</p> <p>Australian Government:</p> <p>Strategic guidance and management of the program and contracts; development and support during procurement process and program establishment.</p>
ALLIANCE STRUCTURE	<p>Governed by the agreement between the federal and NT governments the alliances consist of a combination of the following:</p> <p>Head Contractor; Developer; Local Construction Firm; Engineering firm; Civil Contractor; Specialist Trade Contractor; Building service company; and Suppliers</p>
ALLIANCE DELIVERABLES	<p>The program alliance method led the Australian and NT Governments to select and engage professional services including:</p> <p>Program management services; Cost management; Design coordination; Construction management; Financial Audit services; Value for money; and economies of scale</p>
TIME FRAME	Completed by the end of 2013
HOUSING DELIVERABLES	<p>New Houses = 750 Houses</p> <p>Rebuilds = 250 Houses</p> <p>Refurbishments = 2500 Houses</p>
ALLIANCE DELIVERY METHOD	<p>Phase 1</p> <p>Selection of alliance partners:</p> <p>Selection and engagement of for a collaborative alliance construction consortia through public and select tendering. Non-competitive environment to encourage partnering, innovation and commitment.</p> <p>Public Expressions Of Interest (EOI) in May 2008</p> <p>Selective Request For Proposal (RFP) in June 2008</p> <p>Detailed Selection and evaluation panel</p> <p>Engagement and development of alliance terms</p> <p>Phase 2</p> <p>Planning and Development</p> <p>Develop and plan cost and scope packages based on community engagement</p> <p>Employment & Workforce Development including minimum of 20% local indigenous training & employment</p> <p>Detailed design and planning</p> <p>Phase 3</p> <p>Delivery/ Construction:</p> <p>Procurement of local services</p> <p>Delivery of Houses</p> <p>Construction, refurbishment and rebuilding of houses</p> <p>Continuous community involvement, training and employment</p>
ALLIANCE PARTNERS	<p>Earth Connect Alliance:</p> <p>Canstruct Pty Ltd; WorleyParsons Services Pty Ltd; Force 10 International Pty Ltd; Greene & Associates Pty Ltd; and Ostwald Bros. Pty Ltd</p>

	New Future Alliance: Leighton Pty Ltd; Broad Construction Services Pty Ltd; Opus Pty Ltd; and Ngarda Civil & Mining Pty Ltd
	Territory Alliance Partners: Sitzler Pty Ltd; Laing O'Rourke Australia Construction Pty Ltd; McMahon Services Australia Pty Ltd
	With a Sub Alliance Participant: Compass Group (Australia) Pty Ltd
INITIAL BUDGET	Australian Government: \$ 547 Million NT Government : \$ 100 Million Additional: \$ 25 Million Total = \$672 Million
ESTIMATED UNIT COST (Standard unit cost per dwelling, as determined from previous programs and cost planning)	New House Target Cost: \$350,000 Estimated Regional Package Cost: \$30-\$50 million

4.3 Principles for Success

Identification of the primary issues with remote indigenous housing is the first step in developing the objectives and desired outcomes for a housing program. The focus of the procurement and contract system must successfully address the issues present through the delivery of a housing project that achieve sustainable housing and associated outcomes (Tipple and Willis, 1991). Through thematic and statistical analysis of literature, government surveys and statistical reporting, a number of themes were established as key principles for success in the procurement of IH. These principles affect the success of remote housing programs and are critical issues that can assist in improving the outcomes of the remote IH situation in the NT. Each of these principles are highlighted and discussed below in order to elaborate on their success in delivering the SIHIP Project Alliance. 11 principles were identified in total, however, due to the word limit constraints of this paper, only the first three are reported in detail here. The 11 principles for success in the SIHIP Project Alliance are:

Cultural and Social considerations;	Sustainable Practices;
Design Suitability;	Effective Program Management;
Economic Development;	Construction Standards; and
Community Involvement and Consultation;	Time.
Regional Focus;	
Value for Money;	
Adaptability;	

The following discussion of some of the key principles for success draws upon the outcomes and results of the SIHIP in accordance with 'The Review' (FaHCSIA, Australian Dept. of Families, 2009) and the PRA (SIHIP- Post Review Assessment, March 2010). These, together with the understanding of the Alliance system used in the SIHIP, discusses the degree to which the SIHIP Project Alliance addressed the key principles of remote Indigenous Housing.

4.3.1 Cultural and Social Considerations

The strong and unique cultural principles that guide the lives of Indigenous Australians should be a major consideration in any attempt to develop the built environment and community infrastructure which these people inhabit. The SIHIP Alliance has a defining characteristic of utilising early contractor involvement and community consultation during the preliminary stages of the Alliance. In these early stages preliminary scope of works are drafted and designs are developed based on the specific needs of the occupants and surrounding community. However this is completed on a large scale for each Alliance partner in their respective geographical area, for the entirety of the communities in that area. Indigenous culture is unique in its connection to the land and living environment, and each local area may have different cultural beliefs in connection to their landscape and location (Heppell 1979). The SIHIP addressed this through is strong emphasis on community involvement for each separate locality and community site, in attempt to ensure cultural appropriateness of the housing solutions (FaHCSIA, Australian Dept. of Families 2009).

Despite the emphasis on community consultation the Alliance governance structure does not demonstrate a substantial level of indigenous decision making into the management processes. This could be attributed to the consideration of cultural and social issues being of lower importance in the Alliance system. These considerations are likely overtaken by the cost considerations and attempts to utilise economies of scale for the entirety of the program. It is clear that the program is responsive to the communities cultural and social needs, the balance was lost between the endeavour to keep unit costs per house down, to meet targets over the life of the program. Overall the Alliance model ensures cultural and social issues are considered at a moderate level.

4.3.2 Design Suitability

As fundamental criteria to the success of the remote indigenous housing projects, the design and planning of the dwellings is affected by the procurement process. The design considerations are broad for remote housing including cultural and social elements (as above), climate, remoteness, and cost factors. The Alliancing framework provides for improved consideration for appropriate design through its consultation processes and the commitment to cultural and social issues.

The attraction of high quality designers, architects, planners and engineers through the Alliancing approach ensures commitment to appropriate designs and planning of communities. This is opposed to traditional forms of procurement which are based on competitive tendering and contractors are chosen heavily on price based criteria, and not their contribution to successful designs (Noble 2007). Early involvement of the contractors and consultants in the development stages of the Alliance, is utilised in workshops to propose potential designs leading to constant development of designs that are suited to the specific site conditions and occupant needs. Alliance teams develop a 'Project Development Report' for each of the regional project

locations, which defined the scope of works, designs and cost packages to provide value for money and meet the needs of the community. These processes involve large levels of community consultation and effectively are aimed at improving the suitability of the houses to achieve the objectives of the program (Dept of Treasury and Finance, 2006).

4.3.3 Economic Development

The SIHIP aimed to contribute to the economic development of the local communities, the state and federal economy and the Non-Owner Participants in the Alliance teams. The introduction of the large scale Project Alliance system into the NT government public works program is still in its early stages, this enables the NT government to develop new skills and resources that are required for the implementation of the SIHIP Alliances. Taking on responsibility and managing risk that is not generally borne by the public sector, additional resources, training and staff are required. Bringing new skills and experience in the innovative contract system, the Project Alliancing approach enables the economic and corporate development to the public and private sector of the NT. The use of Project Alliancing generally attracts large and innovative national and multinational participants, whom bring their resources to the NT to contribute services and contribute to the workforce and economic development of the Territory.

Across the life of the program, Alliance partners are in agreement to reach targets of local indigenous training and employment, as a major commitment to achieving improved social and economic outcomes for the region. The targets were set to reach 20% indigenous and local employment and training across all projects, and at the time of this research these were being exceeded in the Tiwi Islands and Tennant Creek projects. The training and development of the economy in the remote communities is integral in achieving long-term outcomes, the SIHIP must ensure that the development of the workforce and community is continued after the completion of the project, with integration of property management, maintenance and asset management into the program giving the community an understanding of the processes and principles of building and their maintenance. Further to the effect of the Alliance on economic development, the processes involved with selection and sourcing of resources, together with the level of works taking place in these otherwise isolated communities can in the short term provide economic stimulus to the area, and hopefully foster the development of future business endeavour and wealth creation.

5 Conclusion and Further Research

The standard of living conditions for indigenous Australians in remote areas of the NT is widely acknowledged as below the standard of the remainder of the population. Past programs have failed to address the problems of overcrowding, poor living conditions, homelessness and severe shortage of appropriate housing across the NT. The delivery of remote Indigenous housing is in need of reform to address the mounting problems and continuing disadvantage of remote Indigenous communities. The principal means for achieving successful housing outcomes lies in the procurement of design, construction, management and maintenance services to deliver housing and associated infrastructure. Via a case study analysis of the SIHIP Project Alliance, 11 principle factors were identified as being critical for the projects success. This paper identified all 11 of these principles, but due to word limit constraints, reported in detail on 3 of them, namely ‘cultural and social considerations’, ‘design suitability’ and ‘economic development’.

The SIHIP, which is the largest scale IH program, is improving the outcomes of remote Indigenous housing. The paper identified Project Alliancing as providing a departure from the traditional contracting methodologies and subsequently offered a range of benefits toward the improvement of IH outcomes in remote areas of the NT. The SIHIP Alliance framework was found to encourage collaboration, innovation and allowed all participants to work as an integrated team towards reaching the projects objectives. Characterised by the arrangements which ensure risk and responsibility is shared across all participants and a pain/gain-share payment system the Alliancing approach collectively ties project objectives together and ensures all participants are working together towards goals and either win or lose as a group. Repeatedly defined as being suited to complex, dynamic projects that have an undefined scope of works and potential to change substantially over time, Alliancing is as an appropriate procurement method to be applied to the ever-changing problem of remote IH delivery.

Project Alliancing is a pioneering method of procurement in the Australian government and SIHIP is the first time this approach has been applied to a housing or other Capital Works program in Australia's NT. Overall the innovation in procurement methods such as Alliancing has the potential to contribute successfully to remote indigenous housing and significantly improve future outcomes. Through greater experience with relational contracting systems and commitment from industry and the public sector, Project Alliancing will be instrumental in delivery of sustainable housing programs for remote Indigenous Australians, with flow on effects into the development and principles of closing the disadvantage gap.

5.1 Further Research

These findings warrant further research into remote Indigenous Housing procurement. SIHIP has shown that Project Alliancing has the potential to improve the outcomes of challenging and dynamic projects such as indigenous housing and relational contracting methods also have the ability to change the way in which other large-scale Public Works construction projects are procured. To improve the knowledge base of IH procurement approaches the following areas are recommended for further research:

Reporting on the other 'success' principles not discussed in detail in this paper;

Further analysis of Alliance outcomes from SIHIP on completion in 2013;

Tailored contracting and procurement methods for remote indigenous housing;

Investigation of the non-owner participants' experiences in IH projects; and

Assess the impact of policy and legislation on standard methods of procurement for IH and the development of relational contracting standard conditions in Australian construction contracts such as AS2124 and GC21.

Impact of Bureaucracy on Project Change – A Framework for Evaluation

Kenneth Sullivan, MBA, PhD¹, Dean Kashiwagi, MSc, PhD¹, and Kristen Barlish¹

Abstract:

Changes in construction projects represent risks for all project stakeholders, but without uniform and reliable metrics to record and compare, changes are subject to opinions and cannot be easily analyzed. This paper proposes a framework for the evaluation of the impacts of an environment on project change. Bureaucratic and Less-Bureaucratic environments are used as case studies for the application of this framework. The impact of the environment on project change is calculated based on 1) Dominant metrics and KPI; 2) Clear classifications of the sources of change; and 3) Sound analyses regarding the recorded outcomes. This paper illustrated the difference between these two environments by comparing their rates of change and suggested areas of improvement. The four (4) metrics to quantify change were: 1) Cost; 2) Schedule; 3) Client satisfaction or quality rates; and 4) Quantities of types of changes; and the four (4) metrics to classify the source of change were: 1) Client; 2) Contractor; 3) Designer; and 4) Unforeseen. The results indicated that there was a greater percentage differential between schedule delays versus cost impacts of the two environments. Additionally, the client was the greatest source of change, specifically schedule changes in Less-Bureaucratic environments.

Keywords:

bureaucracy, environmental impact, performance, performance metrics, project change

1 Introduction

The construction industry has been portrayed as inefficient and resulting in many project changes by sources such as Ibbs *et al.*, 2007; Thomas, 2010; Thomas and Napolitan, 1995; Wambeke *et al.*, 2011. Most of these sources identified the causes of change, but experienced challenges in quantifying the resultant inefficiencies. Measurable and quantifiable data regarding project changes is of use to the industry in order to properly analyze the rise and fall of the projects with respect to change and its causes.

The proper measurement of project change via performance metrics, coupled with the characteristics of the project's environment, would provide better insight into identifying the main sources of change and an estimate of the impact. Commonly, contractors will blame losses due to change and productivity on the client, whereas the client is likely to blame the contractor (Ibbs *et al.*, 2007). Furthermore, measurement of these factors and attributes of the environment in which these projects operate would provide an analysis of the impact that particular environment, specifically bureaucratic, has on project change. It has been stated that there are no current studies that definitively report quantities of change, their impacts, and potential causes (Ibbs *et al.*, 2007; Thomas and Napolitan, 1995).

Without proper classifications of the causes of project change and the quantification of their impacts, analyses cannot be carried out across different projects and environments comparing the causes of change, impacts of change, and matters to alleviate project change. The main reasons as to why this has not been easily carried out are lack of uniformity and reporting of data across projects and environments regarding: 1) Metrics or KPI; 2) Classifications of the sources of change; and 3) Sound analyses regarding the recorded outcomes. This paper will properly address these problems as well as define proper metrics and classifications of the main sources of change and apply this framework to projects in both Bureaucratic and a Less-Bureaucratic Environments for comparisons. By first defining bureaucracy, describing Bureaucratic and Less-Bureaucratic environments, and then utilizing two contrasting case studies to illustrate these differing environments, this paper compares their respective project outcomes and environments noting their rates of change, and suggests areas of improvement.

The questions that this paper addresses are: 1) What are the valid KPIs and sources of change to be utilized for a comparison of projects; 2) What are the results when valid KPIs and sources of change are applied to projects within two differing environments (Bureaucratic and Less-Bureaucratic); and 3) What characteristics make either Bureaucratic or Less-Bureaucratic environments more conducive to reduced changes? In the following summary and analysis, these questions will be answered as well as recommendations provided.

2 Literature Review

2.1 Research Problems Addressed

The determination of what and who to measure are challenges in quantifying changes and making recommendations. Models such as: lost productivity method, measured mile analysis, baseline productivity analysis, system dynamic modeling, earned value analysis, sampling methods, and comparison methods are commonly referred to (Ibbs *et al.*, 2007), but inconsistently used across case studies. More commonly, construction projects are measured via Key Performance Indicators (KPI). However, KPIs are often not uniform across projects and result in confusion regarding what should be measured, how it should be measured, what are the sources of change, and how to evaluate project success or failure. Furthermore, with these suggested models and KPIs, few studies utilize internal and external project data with measurable results to validate them.

2.1.1 Current Metrics

According to Cox *et al.*, Key Performance Indicators (KPIs) are compilations of data measures used to assess the performance of a construction operation or a particular task (2003). Generally, these measures have comparisons of estimated or planned and actual or completed quantities. Furthermore, the measures are often of both the intangible and tangible types. These generalizations make comparisons of KPIs quite challenging across projects and organizations. Cox *et al.* identifies that current models fail to identify which indicators will accurately portray the changes in performance (2003). This paper holds that the quality, rather than the quantity, of measurements should be upheld.

The KPI suggested by the majority of the literature are not incorrect, rather, they are not precise enough and result in an overload of subjective measurements. Examples of qualitative KPI suggested by the literature are: safety, turnover, absenteeism, and motivation (Bassioni *et al.*, 2004; Cox *et al.*, 2003; Ibbs *et al.*, 2007). In contrast, examples of quantitative KPI suggested by the literature are: units/man-hours, dollars/unit, cost, on-time completion, resource management, quality control, percentage complete, earned man-hours, lost time accounting, and punch list (Bassioni *et al.*, 2004; Cox *et al.*, 2003; Ibbs *et al.*, 2007). A survey and analysis revealed top rated KPIs in order of: on-time completion, no preference, units/MH, safety, and quality control/rework (Cox *et al.*, 2003). A common and concise list of KPI would be beneficial for proper project comparisons of change.

Two common references for quantification of KPIs and comparisons are industry studies or databases and construction productivity claims made in court; however, both have limitations of application. Industry studies and databases can be misleading, as Thomas found a range of error in predicting the inefficiency for a single project to be 10-40% differential (Thomas, 2010). Loss claims can become a source data and comparison for other projects, as contractors file and attempt to quantify cumulative impact of multiple change orders and productivity (Jones, 2001; Gulezian and Samelian, 2003). However, there are challenges in utilizing these measurements due to their litigious nature and highly project-specific variables.

2.1.2 Problems: Sources of Change

Change is commonly defined as any deviation to the original scope of work (Ibbs *et al.*, 2007; McEniry, 2007; Thomas and Napolitan, 1995). The KPI previously mentioned focuses more on intangible qualities, rather than those easily quantified. Thus, there is a misalignment of KPI and how change is measured. Additionally, KPIs are not assigned a source responsibility, thus project changes are measured as an overall value and not particularly attributed to a specific source. Changes should be measured with respect to the responsible parties or party for the deviation, instead KPI are commonly followed to measure the outcome versus the change itself.

The inefficiency caused by change has been most commonly associated with the cost of change orders. Estimates of the impacts of change vary from: 6 percent due to design errors, 30-60 percent total, 11 percent total (Ibbs *et al.*, 2007). This range in percentages suggests that metrics should be further divided into simpler categories. A total value can be misleading as it may be due to specific types of changes and have multiple sources. Knowing who is responsible is an important tracking mechanism if the rate of change has any hope of improving. Properly

identifying and assigning responsibilities can assist in accessing the efficiencies of each responsible party, or lack thereof.

Some studies have attempted to create a model to evaluate the performance of entire organizations or entities in construction with regard to overall and managerial impacts (Horta *et al.*, 2010; Yu *et al.* 2007). The construction industry and the businesses that it consists of are both similar and different to the common organization. For example, most businesses would focus on profitability as their main metric, while it is suggested that construction businesses should focus more on resource allocation and utilization measures (Yu *et al.*, 2007). The measurement of this becomes complicated; however, there exists a multitude and variety of resources and no direct tracking mechanisms. Rather than tracking organizations, projects the organization completes should be tracked with respect to changes, sources of change, and impacts, analyzing via comparisons if the environment itself is a hindrance.

2.2 Bureaucracy: Defined

Bureaucracy is a characteristic of an organization that, for the purposes of this paper, can be observed to have an impact on overall project performance within an organization and is generally a prohibitive quality. Bureaucratic organizations are often seen as being inefficient (Horta *et al.*, 2010; Luo and Junkunc, 2008). Thus an analysis of this particular environment would prove insightful of some of the more negative impacts and changes that could occur, according to its definition.

2.3 Bureaucracy: Highly-Bureaucratic Organizations

As an active scholar on the topic of public management, Pollit examined a series of case studies of various organizations and their bureaucratic aspects, finding the following characteristics of bureaucratic organizations (2009):

There is a clear hierarchy of offices;

The functions of each office are clearly specified;

Officials are appointed on the basis of a contract;

Officials are selected on the basis of a transparent set of requirements for certain levels of education/training;

They are paid a salary, linked to hierarchical position, and accrue pension rights;

Their posts are their sole or major occupations;

There is a career structure, and promotion is by seniority or merit (or some mixture), decided by the superior ranks;

Management of the office relies upon written files – decisions are inscribed in an official record;

The official may not appropriate the post or the resources which go with it;

The official is subject to unified control, and a disciplinary system;

The whole organization is rule-governed, and those rules are law or law-like.

From this, it can be seen that bureaucracy depends on the structure of the organization itself. The key tenants are: continuous central authority, a written record at the core of operations, and hierarchically defined rules and precedents. These factors may not seem unique to the case studies presented in this paper; rather, they are quite indicative of most organizations (Pollit, 2009).

2.4 Bureaucracy: Less-Bureaucratic Organizations

Pollit furthered his research into bureaucracies, identifying what he termed “post-bureaucratic” organizations that have put in place a conscious replacement for a traditional bureaucracy, resulting in increased speed, efficiency, flexibility, committed and more outward-looking outcomes. The move to decreased bureaucracy typically involves one or more of the following innovations (Pollit, 2009):

Hierarchies are flattened. Horizontal connections are emphasized

Significant parts of the organization’s activity are no longer conducted by specific ‘offices’ with a fixed place in the hierarchy, but rather by temporary teams or networks which may include outsiders of various sorts.

Officials are still appointed on contracts, but the nature of these contracts becomes more variable. More are temporary or short term and tied to the achievement of specified goals rather than procedures and responsibilities.

Appointments may still be made on the basis of transparent criteria but the variety of criteria for the variety of roles becomes greater. All sorts of specialists may be hired on all sorts of specialist or local terms. This may well weaken the general sense of uniformity and hierarchy.

Salaries also become less uniform and less predictable. Top executives may be paid spot salaries to ‘reflect the market’. At all levels of the hierarchy performance-related pay (PRP) means that competitive elements are injected;

At all levels, there is more part-time and temporary working. For many in the post-bureaucratic organization their ‘post’ may be only one of the things they do;

There is a career structure, but it may involve jumping from organization to organization, from public sector to private sector and back, in order to ‘get on’. This alters patterns of loyalty, and the depth of experience high-flyers get of individual organizations;

The principle that decisions should be recorded is maintained, but the ways in which such recording takes place have become faster and more varied most notably through electronic systems;

The individual still may not appropriate the post or its resources. On the other hand, the increasing rate of movement between organizations and the increasing rate of part-time working for more than one organization combine to create larger possibilities for conflicts of interest.

The official is subject to control and discipline, but 6, 7 and 9 above all tend to weaken the effect of these controls on a significant proportion of staff;

The whole organization remains rule-governed, but (a) (at least rhetorically), flexibility and initiative are said to be prized more than 'rule-following'; (b) more of the rules are likely to be 'soft' – codes of practice; guidelines, for example; and (c) the rules are likely to change more quickly which also makes them harder to learn and internalize.

The mere existence of rules and regulations is not counter to less-bureaucratic environments. Rather, administrative barriers, including, "excessive documentation requirements, inadequate information on rules and regulations, inconsistent procedures mandated by different departments, lengthy registration or ratification periods, artificially imposed regulatory obstacles, redundant complexity of formalities, absence of a uniform system of fees, taxes, and other charges, complicated processes requiring multi-agency approval, and unsupportive attitudes from public and government institutions, among others" act in opposition to less-bureaucratic environments (Luo and Junkunc, 2008).

Organizations can fall somewhere on the spectrum of highly bureaucratic to a very low level of bureaucracy. The presence and the intensity of the aforementioned factors of: continuous central authority, written record of operations, and hierarchically defined rules and precedents will determine the appropriate level of bureaucracy. If there is a small central authority or a body with low authority over others, a short record or operations that do not rely solely on the record, and rules that depend on core business functions rather than a predetermined criteria or only one previous case, then there is likelihood that the bureaucracy level is low and corresponds to a Less-Bureaucratic Environment for the purposes of this paper.

3 Research Methodology

In order to validate the framework proposed here for the evaluation of the impacts of an environment on project change, it was tested against two different organizations, each with their own environment. Utilizing Pollit's classifications, the organizations' environments were characterized, with one being "Bureaucratic" and the other being "Less-Bureaucratic." The Bureaucratic environment in this analysis had a very large and highly powerful central authority, a lengthy written record of operations, and also an extended hierarchy that defined rules and precedents based on few representative cases. In comparison, the Less-Bureaucratic environment was characterized by lower levels of these qualities and is working more towards what Pollit identified as "post-bureaucratic" (2009). Within these environments, their projects are evaluated.

These organizations were chosen because they presented bureaucratic dichotomies, making testing of the framework presented here most effectual. Additionally, these organizations presented the best opportunities to evaluate multiple projects under the same organization. In this way, variables between projects could be held constant and a large project based could be

evaluated. The environments could test the framework under multiple projects, with their associated outcomes forming the basis of the research for this paper.

3.1 Metrics for these Case Studies

The analyses of project change for this paper held to the concept that any deviation to the original contract should be tracked in the following metrics: 1) Cost; 2) Schedule; 3) Client satisfaction or quality rates; and 4) Quantities of types of changes. Additionally, each change should be categorized according to its source or responsibility in the following classifications: 1) Client; 2) Contractor; 3) Designer; and 4) Unforeseen. The proper change measurement metrics, coupled with the appropriate sources of change form the basis of measurement and comparisons between the Bureaucratic and Less-Bureaucratic environments.

Data on the projects' changes were gathered via excel spreadsheets in which all deviations to cost, schedule, and satisfaction/quality were tracked and validated. These spreadsheets were completed by contractor PMs and reported on a weekly basis throughout each individual project. These deviations formed the main data sources for every project. Once a project received final payment, Client Project Managers were asked to rate the contractors and the process on a scale of 1-10, with 10 being high or satisfied. These closeout surveys were administered to ensure all matters were completed and there were no areas of dissatisfaction or misalignment between the Client PM and the project. Additionally, the surveys solicited feedback and lessons learned by the Client PM based on that particular project.

4 Findings and Discussion

4.1 Data from Case Studies

4.1.1 General Overview

Original costs and schedules for every project were captured in each respective environment and contained in the excel spreadsheets and changes were reported weekly by the contractor PM throughout the project. Percentages were calculated based off of the deviations from the original data established. Comparing Less-Bureaucratic (LB) to Bureaucratic (B) projects, the average proposal costs were within \$200,000, total awarded cost within about \$1,000,000, and their estimated budgets within \$95,000 (Table 1). The Bureaucratic environment had nine projects, and the Less-Bureaucratic environment had thirty-four projects. The similarities in their projects' sizes and costs make these two environments valid case study comparisons to apply the framework of change metrics and source classifications.

Table 1. General Overview

Metric	LB	B	Δ
Total Number of Projects (Completed and In-Progress)	34	9	25
Awarded Proposal Cost (submittal total):	\$ 9,880,692	\$ 10,083,951	\$ (203,259)
Cost Adjustment:	\$ 981,913	\$ (156,003)	\$ 1,137,916
Total Awarded Cost (sum):	\$ 10,862,605	\$ 9,848,457	\$ 1,014,148
Average Proposal Cost (sum from each project):	\$ 10,717,007	\$ 8,516,517	\$ 2,200,490
Percent Awarded Below Average Cost:	-1%	-16%	14%
Estimated Budget:	\$ 10,387,500	\$ 10,482,672	\$ (95,172)
Percent Awarded Below Budget:	5%	4%	1%

4.1.2 Cost Increases

In the categories measured of: client, designer, contractor, and unforeseen change orders, there was less than 0.7% difference between Less-Bureaucratic and Bureaucratic or no difference at all (Table 2). The Less-Bureaucratic environment had a lower rate in the areas of designer and unforeseen, while the Bureaucratic had a lower rate in the contractor category. The contractor category in the Bureaucratic environment actually experienced a savings, passing it on to the client in the form of a negative change order rate.

Table 2. Metric: Cost Increases

Metric	LB	B	Δ
Overall Change Order Rate	3.9%	3.9%	0.0%
Client	2.6%	2.6%	0.0%
Designer	0.3%	0.4%	-0.1%
Contractor	0.1%	-0.1%	0.2%
Unforeseen	0.3%	1.0%	-0.7%

4.1.3 Schedule Delays

Using the same categories for the origin of change orders, there were greater rates of differential between Less-Bureaucratic and Bureaucratic schedule delay rates than compared to their cost increases (Table 3). Overall data collected for schedule increases showed that the Less-Bureaucratic environment had a 25 percent lower delay rate. The highest differential was in the client category of delay rate, with the Less-Bureaucratic environment experiencing 10 percent more client schedule delays. The designer delay rate was the only rate that experienced a lower Less-Bureaucratic delay rate than the Bureaucratic. Client, contractor, and unforeseen all experienced a higher Less-Bureaucratic delay rate.

Table 3. Metric: Schedule Increases

Metric	LB	B	Δ
Overall Change Order Rate	46.8%	21.5%	25.3%
Client	22.2%	12.2%	10.0%
Designer	3.5%	4.9%	-1.4%
Contractor	5.1%	3.9%	1.2%
Unforeseen	4.8%	0.5%	4.3%

4.1.4 Satisfaction Surveys

Via a closeout survey administered to the Project Manager (PM) upon the close of each of the projects, satisfaction ratings were obtained. Due to the nature of the Bureaucratic projects, they are still being completed and have consequently not received final payment and are in the process of closeout. Since the Less-Bureaucratic projects are finished, all projects have PM satisfaction ratings. Nevertheless, comparing the satisfaction ratings, there is a differential of less than one for PM satisfaction of the vendor, with the Less-Bureaucratic environment having a higher satisfaction. In the last ratings, it can be seen that the Bureaucratic project required more management effort according to the PM than the Less-Bureaucratic projects. The analysis would have been further substantiated if PM performance was rated by the end client or client. However, this type of rating was not possible to obtain, due to organizational restrictions, in both the Less-Bureaucratic and the Bureaucratic environments. Please see Figure 4 – Metric: Satisfaction Ratings below for more details.

Table 4. Metric: Satisfaction Ratings

Metric	LB	B	Δ
Close out Surveys	34	1	33
PM Post Project Evaluation of Vendor	9.5	8.9	0.6
PM effort spent managing the project	3.0	5.0	-2.0

4.1.5 Number of Changes

There was a greater quantity of changes in the Less-Bureaucratic Environment than the Bureaucratic Environment (Table 5). Due to the fact that the Less-Bureaucratic environment had more projects, their greater quantity of changes is not a surprise.

Table 5. Metric: Changes

Metric	LB	B	Δ
Total Number of Changes	139	115	24
Average Number of Changes per Project	4.1	12.8	-8.7
Average PM Change Satisfaction Rating	9.0	9.1	-0.1

4.1.6 Feedback

Another source of data is the comments portion of the closeout survey. PMs are encouraged to provide feedback as lessons learned at the closeout of the project. From the Bureaucratic environment, we can see that PMs had comments relating to their desire to add more time and effort to pre-planning and risk management prior to commencement of construction. Additionally, the PM requested additional time to interact with the contractors and subcontractors, including involvement from the A/E. Given the nature of Bureaucratic companies wanting to exercise their authority, follow their record of operations, and hierarchically defined rules it is not surprising that they wanted to impose this with their contractors. The feedback from the surveys further substantiates the nature of the Bureaucratic environment in wanting to try to control and change things.

4.2 What are the valid KPIs and sources of change to be utilized for a comparison of projects?

Change was seen as any deviation to the original contract and was tracked via the metrics: 1) Cost; 2) Schedule; 3) Client satisfaction or quality rates; and 4) Quantity of changes. Additionally, each change was categorized according to its source or responsibility in the following classifications: 1) Client; 2) Contractor; 3) Designer; and 4) Unforeseen.

4.3 What are the results when valid KPIs and sources of change are applied to two projects with differing environments (Bureaucratic and Less-Bureaucratic)?

Despite having fewer projects, when compared to the thirty-four Less-Bureaucratic projects, the nine Bureaucratic projects experienced similar project outcomes in terms of cost, schedule, satisfaction, and change impacts. The total dollar value of the Bureaucratic projects was in line with the Less-Bureaucratic projects, thus making a valid comparison. In terms of cost impacts, the Less-Bureaucratic projects out-performed or were equal to the Bureaucratic projects. Less-Bureaucratic projects experienced the largest differential (0.7 percent) in the unforeseen change order category. In terms of schedule delay, Bureaucratic projects were timelier in order of client, unforeseen, and contractor. In the schedule delay of designer, Less-Bureaucratic projects were timelier. Overall, Less-Bureaucratic projects had a lower change order rate (except for the contractor category) and Bureaucratic projects had a lower schedule delay rate (except for the designer category).

In both environments, client based cost and schedule impacts were the highest. The effect that client-driven decisions can have on projects is easily seen in both contrasting environments, the client is the largest change. Thus, being familiar with the environments that these projects

operate in is critical to determining how to impact sources of change. The concept that the client is the largest source of change is contrary to some of the literature (Ibbs *et al.*, 2007). These client-impacts are further exacerbated by the level of bureaucracies in these organizations and are transferred to their projects. Upon review of the changes, certain client-driven factors were outside the purview of the contractor and uncontrollable. Examples of this type of change included: added scope, risks associated with added scope, security issues, and additional organization's funds become available. In fact, changes abound in both Bureaucratic and Less-Bureaucratic environments. Increase in funding may become available and allow more scope to be added to a project, which is a risk with the client as the source classification.

4.4 What characteristics make either Bureaucratic or Less-Bureaucratic environments more conducive to reduced changes?

Schedule shows a higher percentage of change occurring in comparison to cost, and attention should be paid to this rate. The schedule is consistently a major factor of concern for all project types: Less-Bureaucratic and Bureaucratic. As Wembeke *et al.*, emphasized, schedule impacts can have major effects that manifest themselves downstream on a construction project (2011). More attention should be paid to the schedule and factors that may affect future changes.

As noted in the response to question 2, client-initiated cost and schedule changes accounted for the largest amounts of deviations in all projects, Less-Bureaucratic and Bureaucratic. This finding suggests that more attention should be paid to accounting for potential changes the client will make in the future. The contractor cannot be expected to know all changes that will come about, nevertheless, awareness of this prevalent effect a client can have on a project will enable contractors to plan more appropriately. In this light, measuring and documenting performance becomes essential, as well as pre-planning for potential changes.

The mitigation and eventual elimination of the most prevalent factors of schedule changes and client-initiated changes will facilitate more successful project outcomes. To alleviate some of the client-initiated changes, environments should be fostered to encourage: awareness of the client to the severity of impacts of changes later in the project versus upfront, client to be constantly providing feedback to the contractor of potential changes, project scopes to be more clearly delineated at the start of the project, and, if changes must be made, they are not in excess to cause poor project outcomes. In most cases, the contractor has the capability to minimize risk, despite who caused it (Ibbs *et al.*, 2007). Thus, the contractor should utilize their expertise to minimize the impacts of change. Overall, if the contractor is more informed of potential changes, time is allotted to plan for these changes and risks, and their impacts are minimized upfront, projects can be more successful in these environments.

5 Conclusion and Further Research

A framework for the evaluation of the impacts of bureaucracy on project change was created, based on: 1) Dominant metrics and KPI; 2) Clear classifications of the sources of change; and 3) Sound analyses regarding the recorded outcomes. By first defining bureaucracy, describing Bureaucratic and Less-Bureaucratic environments, then utilizing two contrasting case studies to illustrate these differing environments, this paper compared their respective project outcomes and environments noting their successes or lack thereof, and suggested areas of improvement.

The four (4) metrics were: 1) Cost; 2) Schedule; 3) Client satisfaction or quality rates; and 4) Quantities of types of changes and the four (4) source classifications were: 1) Client; 2) Contractor; 3) Designer; and 4) Unforeseen.

Measurements showed a very small percentage differential for cost impacts between Less-Bureaucratic and Bureaucratic projects and a larger differential in schedule impacts. In the metric of cost impacts, there was less than 0.7% difference between Less-Bureaucratic and Bureaucratic projects or none at all. For schedule impacts, there were greater schedule delay rates than compared to their cost increases. The highest differential was in the client category of delay rate, with the Less-Bureaucratic environment experiencing 10 percent more client schedule delays. The designer delay rate was the only rate that experienced a lower Less-Bureaucratic delay rate than the Bureaucratic. Client, contractor, and unforeseen all experienced a higher Less-Bureaucratic delay rate. Less-Bureaucratic projects had a higher satisfaction rating, and were reported to require less management effort. Lastly, there was a greater quantity of changes in the Less-Bureaucratic Environment than the Bureaucratic Environment.

As the client category of change was the greatest, strategies for improvement should focus on this area. These environments could be improved upon and result in better project outcomes if client-driven changes were more predictable, transparent, and timely as well as if schedule impacts were minimized via proper communication and real-time tracking. As a result of this tracking, the Bureaucratic and Less-Bureaucratic case study environments are interpreting these project outcomes and are currently looking at strategies to improve their environments and minimizing the impact of project change. Understanding the type of change and the source of change has given these environments an opportunity and level of visibility not previously achieved.

Additional case studies that follow this framework of KPI and change source classification would further substantiate project and environmental comparisons. Projects would have to follow the four (4) metrics and the four (4) source classifications. Future research should also focus on potential strategies to alleviate the impacts of project changes, specifically client-driven. Innovative contracting strategies, delivery methods, and procurement approaches (Kashiwagi, 2011) should be investigated for their potential to alleviate changes in both Bureaucratic and Less-Bureaucratic environments that negatively impact projects.

6 Acknowledgement

The authors of this paper would like to acknowledge the two organizations analyzed here, which will remain anonymous, as well as the numerous students that contributed to the data gathering over the years of their projects.

Organizational Change Models: A Critical Review of Change Management Processes

Sullivan, Kenneth; Kashiwagi, Dean; Lines, Brian

Del E. Webb School of Construction, Arizona State University, Tempe, AZ
PO Box 0204, Tempe, AZ 85287

Email: Kenneth.Sullivan@asu.edu

Abstract:

Planned organizational change processes are of increasing need for organizations to maintain their competitive edge in today's global economy. Yet planned change efforts have been documented to have failure rates between 50-70 percent. Thus management skills and training in successful change processes is of high value. This article provides a critical review of organizational change models existing in the literature. Eleven literature change models were combined into a consolidated model of organizational change to identify the consistency in current research on this topic. The models were also analyzed according to their implementation (or lack thereof) into real-time change processes as well as documentation of performance information validating their success. Based upon these initial findings, areas of opportunity are identified to guide future research efforts towards improving the processes for planning and implementing organizational change.

Keywords:

change management, change model, organizational change, performance measurement

1 Introduction

Global competition has become ever more disruptive to organizations, and change is ever-present reality that affects all organizations at both the operational and strategic levels (Hamel & Breen, 2007; Todnem, 2005). Organizations worldwide are impacted by an accelerated pace of change efforts that occur in many forms, including restructuring, reengineering, mergers and acquisitions, downsizing, and the introduction of new technologies (Armenakis et al., 1999; Walker et al., 2007). Organizational change has become congruent with organizational strategy, and the effectiveness with which organizations manage change has become a critical element in their ability to maintain a long-term competitive edge.

Although the need for organizational change has never been greater, undertaking and implementing change is an extremely difficult task that is often met with failure. Many sources suggest that more than half of all change efforts fail to accomplish their original intended purpose (Choi & Behling, 1997; Kotter, 1995; Maurer, 1996; Pascale et al., 1997; Self &

Schraeder, 2009). Balogun and Hope Hailey report the failure rate for change initiatives to be as high as 70 percent (2004).

In response to this problem, this paper examined the current literature research on organizational change, specifically focusing on proposed change management models that provide systematic processes for planning, implementing, and institutionalizing organizational change. A critical review of the foremost change models was provided to identify a consolidated framework for managing change efforts as supported by the past 25 years of research theory and experience in change management practices. Further analysis of the literature change models change identified gaps in the current research, which resulted in important conclusions about the needed direction of future research. Among these conclusions was the opportunity to implement planned change processes in real-time initiatives to improve organizational efficiency. The results and impacts of such research should be documented with performance information to provide empirical validation of change management research.

2 Organizational Change Research

As organizational change has become an increasingly important factor of success for companies worldwide, the only way for an organization to be “ready” for change is by having people and structures that are prepared for and capable of change (Luecke 2003). Within this environment, the role of the managers has evolved such that they are typically the people who are responsible for changes that take place (Burnes 1992). Therefore a manager’s ability to effectively plan and manage change has essentially become a required skill, and consequently their true effectiveness and competence is being measured differently than in the past (Burnes 1992). Companies have recognized that ineffective managers negatively impact even well-designed plans to improve organizational performance (Luecke 2003). In fact, American managers are often criticized for their propensity to focus on short-term, “quick-fix” solutions to organizational problems, which are not effective ways to achieve lasting change (Kinicki & Kreitner 2006). As a result, proficiency in change management practices is an extremely valuable skill for modern managers to possess.

In order to support the further development of change management practices and training, the objective of this paper is to review effective ways to manage the planned change process that have been proposed in the literature by organizational change researchers and consultants. Eleven prominent literature models of organizational change were reviewed to understand currently accepted change management knowledge and consolidate this knowledge into a single model of planned change. Included among the models reviewed were those proposed by: Bullock & Batten (1985), Nutt (1986), Hunsucker and Loos (1989), Judson (1991), Burnes (1992), Kanter *et al.* (1992), Kotter (1995), Galpin (1996), Armenakis *et al.* (1999), Moran and Brightman (2001), and Luecke (2003).

Yet before delving into a deeper review of suggested methods to effectively implement and manage change, it is important to first differentiate between the following phrases and topics exist within the field of organizational change research: organizational change (OC) refers to the overall activities that occur during an individual project or change initiative that improves performance of the organization. Typically project-based, one-time endeavors aimed at addressing an overall goal in the organization (McNamara 2011). OC is contrasted with

Organizational Development (OD), which is a large scale, more long term process of improving organizational effectiveness over multiple change activities.

Change management practices include the specific approach or methodology used to implement an organizational change project, program, or overall effort. Planned change follows clear goals that are set for the change effort and a planned, structured, and explicit approach is utilized (McNamara 2011). Unplanned change occurs when the overall vision may or may not be known, and the change itself is an unplanned and implicit natural progression (McNamara 2011).

3 Research Methodology

Each of the literature models reviewed presented a series of process steps to systematically approach, initiate, and implement organizational change. For each model, the authors outlined the process steps that were proposed in addition to major sub steps. The purpose of breaking each model down into its individual sub steps was to directly compare all the case studies based upon the change process components they included. For example, Judson's Five-Phase Change Process, which was based upon Judson's more than 40 years of experience in change management, was broken into the following process steps:

Analyzing and planning for the change.

Change management group with senior management and other managers and supervisors involved as well as staff specialists.

Understand the basis and justification for the change and determine goals and strategy.

Plan all elements of the change, prioritize and schedule events.

Communicating the change.

Educate the reasons and benefits of the change along with the plan of action.

Gaining acceptance of new behaviors.

Via rewards, persuasion, negotiation, bargaining, or participation.

Changing from status quo to a desired state.

Consolidation and Follow-up

Regularly measure and assess the effectiveness of the change.

This process was repeated for all eleven models of change, and all models were aligned side-by-side in tabular form. A gap analysis was performed to identify similarities, differences, and determine the overall consistency between models. Specific categories emerged once the sub-steps were aligned, and these emergent categories became the process steps that made up the consolidated literature model of organizational change.

3.1 Defining the Steps Within the Consolidated Literature Model

Each of the steps within the resulting consolidated model of organizational change was analyzed to determine the total percentage of the literature change models reviewed that incorporated that specific step. For example, it was found that 64 percent of the change models reviewed emphasized the need for a core team to lead the change effort. The individual process steps and their consistency across organizational change models in the literature are shown in Table 1. The consolidated literature model of organizational change resulted in a comprehensive change management model composed of twelve individual process steps within three broader phases of change implementation: Planning and Initiation, Implementation, and Institutionalization. Each of the individual process steps represents a component of the organizational change process. The scope of each step was defined along with a summary of literature model recommendations on how to best carry out the different components of the change management process.

Table 1. Consolidated Model of Organizational Change From the Literature Analysis

Consolidated Literature Model of Planned Organizational Change	Model Consistency
Phase 1 - Plan & Initiate	
1. Actively Create Motivation for Change	64%
2. Analyze Status Quo Problems & Needs	82%
3. Identify Desired Solutions, Goals, or Vision	91%
4. Establish a Core Team to Lead Implementation	64%
5. Secure Executive Support	45%
6. Convey the Change Message	64%
7. Identify Readiness and Manage Resistance	55%
8. Plan the Implementation Strategy and Tactics	64%
Phase 2 - Implement & Measure	
9. Implement on a Test Basis	55%
10. Implement Full Change Program	91%
Phase 3 - Institutionalize	
11. Transition to Institutionalization	82%
12. Long-Term Measurement	36%

3.1.1 Actively Create Motivation for Change

The first step in the consolidated model for planned change was to create a sense of urgency among employees and create the general desire to change. In creating the initial motivation to embark on a planned change effort, change agents may examine the internal and external conditions of the organization and realize the need for change exists. The focal point of this stage is to recognize the need to change in such a way that it acts as a catalyst to motivate the pursuit of change. This step does not involve in depth analysis of current practices or set a specific vision of change, but rather aims to create a broader sense of urgency within the organization to recognize the need to support change efforts.

3.1.2 Analyze Status Quo Problems and Needs

The purpose of this step is for change managers to analyze existing business processes and external conditions to determine specific areas of weakness for the organization to overcome. Managers may also enlist employee participation during this step to compile a more thorough understanding of problems within the organization. The end result of this step is to have identified specific problems and root causes that necessitate a change in business practices.

3.1.3 Identify Desired Solutions, Goals, and Vision

In response to the problems that necessitate change, a vision must be created to address the goals and solutions that are desired. This step primarily focuses on determining how the organization should operate and envisioning how this future state would look once the change effort is successful. This step does not yet call attention to specific implementation strategies or detailed tactical planning of the formal change process.

3.1.4 Establish a Core Group to Lead the Effort

For the purpose of this step, a core group was defined as a team of managers or other employees who possess operational-level knowledge of the problems and desired solutions. Members of the core group may not follow the typical organizational hierarchy and may not include executives; instead, emphasis is placed on their knowledge of key operational level issues that make them best suited to lead the change effort. Activities of the core group include the day-to-day leadership and management of the change program.

3.1.5 Secure Executive Support

The step of securing executive support was defined to include those literature models that emphasized the importance of gaining assistance or general backing for the change program from executives. Executives include high-level decision-makers who have the authority to generate financial and policy directives. Although executives are not necessarily members of the core group, it was noted that they are still critical that they are bought in to the change program. Executives wield the clout within the organization to legitimize the change with their support and have the power to either sustain or remove the change through financial and policy means.

3.1.6 Convey the Change Message

This step stresses that change managers must give specific attention regarding how the vision of the change is communicated within the organization. Models that included this step typically emphasized the need to frame the change message in such a way that addresses the perspective of those who will be impacted. The purpose of this step is to educate those affected by the change on the basic purpose, goals, and implementation strategy of the change, as well as how they will be impacted the change and why the end goals are beneficial.

3.1.7 Identify Readiness and Manage Acceptance

The literature models recommended that change managers spend time to identify their organization's readiness for change by analyzing potential and actual sources of resistance that may counteract the change effort. This step also consists of any specific actions taken to minimize resistance such as various modes of employee participation, feedback, reward systems,

or political negotiations, all with the purpose of eliminating barriers and creating the conditions for change to occur successfully.

3.1.8 Plan the Implementation Strategy and Tactics

This component of the consolidated organizational change model refers to detailed planning of the technical aspects of how the change will be implemented. The technical aspects include the specific action steps required to enact the change, such as how individual business processes and employee functions change with respect to the organization's previous operational methods. Also considered within this component is ensuring the technical aspects of the change align with the strategic vision and goal of what is meant to be accomplished. Measurements are planned to determine the success of the change, specifically focusing on whether the tactical actions actually achieve the strategic vision.

3.1.9 Implement on a Test Basis

This step was addressed by models that underscored the importance of starting implementation on a test basis, which was defined as any scale that was smaller than the overall intended change program. Starting implementation on a test basis was also characterized by the intent of applying the lessons learned on the smaller scale to refine the change for full-scale implementation.

3.1.10 Implement Full Change Program

This step referred to implementing the change action steps on the fully intended scale or diffusing results of the original trial period into the larger organization. This step ends when the operational modes intended by the change are first achieved, but are not yet institutionalized within the organization.

3.1.11 Transition to Institutionalization

Following the implementation of the full change program and achievement of results, institutionalization consists of formalization or transition processes intended to achieve long-term adoption of the change. This step moves from active implementation of the change program towards formalizing the changed processes as traditional practices. Formalization processes include measures to reinforce and stabilize the change such that it becomes "the way we do things around here."

3.1.12 Long-Term Measurement

Long-term is defined as the time period following the main efforts of implementing and institutionalizing the change program. This final step comes into play when the change is no longer a foremost priority of management or employees and has seemingly been institutionalized within the organization. Maintaining a post-institutionalization, program-wide measurement system is intended to sustain the change once the organization's attention is focused on other items.

3.2 Documented Performance Information in Literature Organizational Change Models

3.2.1 Sources of Information for Model Development

The source of knowledge that was used by the various researchers to develop their respective models of planned change was documented to gain insight into base of knowledge that the literature models were based upon. This analysis was conducted according to four main sources of information used by researchers to develop their organizational change models:

Personal Experience: The model was based upon the researcher's personal involvement in management consulting and change management implementation. Reflection upon their experiences enabled the researcher to propose a model for change.

Literature Review: The source of knowledge used to create the model was a critical review of literature research. This category is limited to analysis and consolidation of previous literature research and theory.

Industry Feedback: The source of information was not related to a specific change effort that would serve as a case study, but instead included more general industry feedback regarding overall experience with change implementation. Managers and other individuals were surveyed and/or interviewed to gain a second-hand understanding of their general experiences with organizational change.

Case Studies: The model was based upon findings from an in depth review of specific planned change efforts undertaken within organizations. Example cases of organizational change were reconstructed in a systematic manner to understand the methods of change implementation. Procedures used to reconstruct case studies of change implementation included interviewing and surveying managers to understand how the specific change process was implemented. The researcher was not directly involved in the reviewed case studies.

3.2.2 Performance Information of Model Implementation

From a research perspective, another important factor in analyzing planned organizational change is documenting whether their performance has been measured in real-time change efforts. In the context of the organizational change models considered in this paper, empirical documentation was equated to the existence of performance measurements. Performance measurements were defined as any metrics that show the level of success achieved through the implementation of a planned change model. In one literature model, performance measurement was as simple as documenting whether the original intent of the change effort was achieved for a "duration of time," whether short or long term (Nutt, 1986). Each of the eleven literature models reviewed in this paper was reviewed based upon their inclusion of empirical performance measurements.

In reviewing the empirical nature of the models, another point of emphasis identified was whether the reviewed models were tested in real-time or if they had been developed retroactively. Real-time testing was defined as any documented instances where the change model was directly implemented as the process used to achieve organizational change. To be considered a real-time test, the model was required to have been identified at the beginning of

the change effort and used as the process steps through which the change was then implemented. Conversely, retroactive development referred to models that were identified after real-time change efforts were executed. In retroactive cases, researchers created the change models based upon past experience, either by analyzing their personal experience, literature research, industry feedback, or case studies to identify the components of a successful change process.

Each of the eleven literature models identified in this paper was reviewed against these two criteria to determine whether they had been empirically documented through performance information and directly applied in real-time change efforts. For this analysis, the criteria were combined into the following four categories:

Real-Time Performance Measurement: The model of planned change was tested from start to finish in an organizational change effort and used as the process for planning and implementation. Real-time performance measurements were made to quantify model success.

Real-Time with No Measurement: The model was directly applied as the process for enacting a change effort, but measurements of success were not documented.

Retroactive with Performance Measurement: The model was created based upon past experience, literature review, or industry case studies and feedback. However, the full model was not directly applied in real-time throughout a change process. Individual instances of success were documented for case studies that were reconstructed and shown to follow components of the proposed model.

Retroactive with No Measurement: The model of planned organizational change was developed based upon past experience, literature information, or industry feedback. The model was not implemented in a real time change effort and no determinants of success were measured.

4 Results and Discussion

4.1 Consistency within the Literature Organizational Change Models

The literature models were compared to determine which individual process steps were most commonly recommended as part of a successful change management process. By analyzing all the individual change management stages included within the models, a view of the overall consistency among the literature research efforts was identified. Results are summarized in Table 3, with each process step of the consolidated model paired with the percentage of literature models reviewed the step was included in.

Table 2. Consistency in Recommended Process Steps in Literature Models of Organizational Change

Consolidated Literature Model of Organizational Change	Model Consistency
Process Steps	%
3. Identify Desired Solutions, Goals, or Vision	91
10. Implement Full Change Program	91
2. Analyze Status Quo Problems & Needs	82
11. Transition to Institutionalization	82
1. Actively Create Motivation for Change	64
4. Establish a Core Team to Lead Implementation	64
6. Convey the Change Message	64
8. Plan the Implementation Strategy and Tactics	64
7. Identify Readiness and Manage Resistance	55
9. Implement on a Test Basis	55
5. Secure Executive Support	45
12. Long-Term Measurement	36

The most commonly recognized components of successful planned change efforts were found to be identifying desired solutions, goals, or vision and implementing the full change program, which were both included within 91 percent of the literature models. 82 percent of the models identified the steps of analyzing the status quo problems and needs and transitioning the change to institutionalization. After these four steps, there was a drop off in the level of consistency between the literature models, with the following four steps suggested by 64 percent of the models: actively create motivation for change, establish a core team to lead implementation, convey the change message, and plan the implementation strategy and tactics. Incorporated into 55 percent of models were the steps of identifying readiness and managing resistance and implementing the change on a test basis. The least commonly identified steps were securing executive support (45 percent) and continuing long-term measurement to sustain the change (36 percent).

4.2 Documented Performance Information of Literature Organizational Change Models

4.2.1 Sources of Information for Model Development

The frequency with which the models used each data set is shown in Table 3. The percentages do not sum to 100 percent because researchers often utilized multiple sources of knowledge to develop their suggested model of organizational change. The majority of the eleven models were created based upon knowledge gained from the researcher's personal experience (55 percent), while slightly less than one-half of the models pulled information and findings from the literature. Three models were developed using lessons learned from industry case studies, while

two included feedback data from industry members who were directly involved in organizational change initiatives.

Table 3. Data Sources Used to Understand the Components of the Organizational Change Process

Data Set for Model Development	
Personal Experience	55%
Literature Review	45%
Industry Feedback	18%
Case Studies	27%

4.2.2 *Performance Information of Model Implementation*

A matrix was created in order to show where the eleven models placed according to real-time implementation and performance measurement (Table 4). Results showed that all of the organizational change models reviewed in the literature were developed retroactively. In order to create change models, researchers primarily reflected upon past management experience, reviewed previous literature research, and analyzed case studies and feedback from previous industry change efforts. None of the reviewed models were shown to have been fully implemented in a change process, so no real-time validation was observed. Furthermore, results show a lack of performance information in the research. Only two change models documented performance measurements showing the success rates of change efforts that followed the model.

Table 4. Empirical Documentation of Organizational Change Models

	Real-Time	Retroactive
Performance Measurements	0%	18%
No Measurements	0%	82%

It must be noted that in saying that none of the models were implemented, the authors do not mean to suggest that none of these models have been used by the researchers who proposed them. The fact is that the researchers who developed these models certainly used various pieces at different times throughout their careers as change management researchers or consultants. Rather, what the authors have documented is the fact that, from a research perspective, the reviewed models were not implemented from the outset of a change process and empirically shown to bring about change. This distinction is important to make, as it clearly reveals that literature models serve as a practical base of knowledge for implementing organizational change, yet have presently shown the direct application of this knowledge within real-time research efforts. As will be concluded later in this paper, the lack of empirical evidence supporting the implementation of these models presents a large opportunity for future research.

4.3 General Discussion

All the change models reviewed contain sound advice as the researcher models reviewed were based upon many years of change management consulting experience. Yet with the high rate of failure in change efforts that is currently documented, along with the fact that the majority of change models were developed retroactively, it may be concluded that these models have not frequently been applied to organizational change efforts. The lack of empirical evidence presents an important opportunity for future change management research: to directly apply organizational change models and their specific components in actual change efforts, and then document the progress and results of the change to demonstrate determinants of success.

The lack of performance information also indicated an opportunity for future research to better define the determinants of success within planned change efforts. Even among the two literature models that were found to document whether success was realized in case studies of organizational change, success was not defined according to quantitative measurements, nor was the time period to properly evaluate success determined. This paper proposes that the impact of change efforts should be chronicled over a long period of time. In 1958, Lewin recognized that a change implemented to achieve a higher level of group performance “is frequently short-lived,” as group behaviour often reverts quickly back to its previous manner (Burnes 1992). Therefore, as change models are implemented to achieve performance goals within organizations, it is important to revisit the program over longer terms to determine whether institutionalization has been achieved. Long-term success was not documented to occur using the reviewed literature models.

5 Conclusion and Further Research

This paper reviewed eleven prominent literature models of change and aligned their process steps into a single consolidated model of planned change. The sources of information used to create the models in the literature were shown to be dominated by the personal experience in change management (used in 55 percent of models) and literature review (45 percent), whereas case studies of change were a much smaller source of information (18 percent). Note that these percentages do not sum to 100 percent since the literature models were often based on multiple sources of knowledge.

These findings identified a need for future research to implement change models in planned change efforts and document success levels. The lack of performance information within the research demonstrated a lack of consensus among researchers in how to define and measure the determinants of success for planned organizational changes. The existing change management database would greatly benefit by documenting these factors through the measurement of performance information in planned change efforts.

The Performance Based Studies Research Group (PBSRG) at Arizona State University views these topics being critical to its research function of expanding performance measurement in the field of organizational change and development. The PBSRG is a world leader in efficient business practices that works with numerous research partners in a wide variety of industries. The PBSRG has developed and tested the Best Value Business Model to increase organizational efficiency by improving procurement processes, project performance, and business management

strategies. The PBSRG specializes in implementing planned change to achieve these results, and has collected extensive real-time data of planned change implementation on the project level. During 17 years of testing the Best Value Business Model, the PBSRG has run over 900 projects at a total value of \$4.6 billion and achieved project success rates over 95 percent. Using the extensive performance information amassed by the PBSRG on projects of planned change, immediate next steps for the research group include providing empirical documentation and real-time performance information regarding the factors of success in implementing planned organizational change.

The PBSRG envisions future research to focus on using performance measurement to facilitate change on the level of organizational development. Within this framework, future research is suggested to focus on broader change efforts that link individual projects through measurement and focus on long-term results to understand institutionalization and sustainability of change.

Building Regulation & Control

Local Authority Liability in New Zealand for Defective Homes

Kenneth Palmer

Associate Professor of Law,
The University of Auckland,
Auckland, NZ

Email: ka.palmer@auckland.ac.nz

Abstract:

The liability of local authorities in New Zealand for the issue of building consents and inspection, in respect of domestic homes where the dwellinghouse or home unit is later proved to be faulty, is assessed. The law in this respect differs from that in the U.K. In *Invercargill City Council v Hamlin* (1996) the Privy Council accepted that the decision of the House of Lords in *Murphy v Brentwood District Council* (1991) declining to impose liability for economic loss did not apply in NZ. But the NZ courts have not extended the duty of care on councils to apply to buildings used for commercial purposes. Recently the Supreme Court of NZ in *North Shore City Council v Body Corporate 188529* (Sunset Terraces & Byron Avenue), has confirmed that local authorities owe a duty of care to the owners of multi-unit dwellings in the issue of building permits, supervision, and code compliance certificates. The duty is owed to both existing and future home owners, but may be reduced by contributory negligence. A 10 year logstop from council approvals applies to claims. In the last decade, problems with leaky homes, through the use of untreated timber and monolithic wall cladding systems, poor design and workmanship, have given rise to a substantial number of claims against local authorities. The provision for claimants of a formal mediation service and adjudication process is assessed. A recent proposal by the Government to assume liability for 25 percent of repair costs, with local councils accepting a further 25 percent, is considered. Conclusions are drawn as to the legal and practical outcomes.

Keywords:

building, consents, council, liability, mediation

1 Introduction

This paper sets out the legal position in New Zealand in 2011 concerning the liability of territorial local authorities (city and district councils) for defective homes.¹⁰⁹ The defects may

¹⁰⁹ Local Government Act 2002 (NZ), s 5 (definition territorial authorities). The LGA establishes the governance structure under which district and city councils are consent authorities for urban building work under the Building Act 2004. Regional councils have limited functions in respect of dam construction. In the Auckland region, the former seven local authorities were amalgamated to form a single Auckland Council (super city) from 1 November 2010: Local Government (Auckland Council) Act 2009. As a unitary authority the Auckland Council is the consent authority for all building work in the region. It has inherited liabilities of the former local authorities.

arise from inadequate foundations and water leaks and other causes. The paper considers the history of the determination by courts of liability, issues relating to the limitation period for claims, and the divergence of New Zealand law from U.K. law.¹¹⁰ The question of liability for other buildings used for commercial purposes, such as hotels and motels is considered. The question of central government responsibility is addressed. The most recent decisions of the Supreme Court of New Zealand in the *Byron Avenue* and *Sunset Terraces* cases (2010) are discussed.¹¹¹ Finally, the systems available for mediating and determining liability under the Weathertight Homes Resolution Services Act are considered, together with a current proposal of government to share in the burden of repair costs.¹¹²

2 History of Local Authority Liability for Defective Homes

In 1972, in *Dutton v Bognor Regis Urban District Council*¹¹³ the English Court of Appeal determined that a builder could owe a duty of care in tort law to a subsequent purchaser of a property which had defective foundations. The builder could be liable even though there was no immediate contractual relationship with the subsequent purchaser. More significantly, the Court determined that the local authority could also owe a duty of care to the subsequent purchaser for failing to carry out inspections with reasonable care. The council could be liable in negligence for this failure of duty. Assuming the builder remained solvent, the question of apportionment of liability between the builder and the local authority could be determined having regard to the degree of responsibility for the damage. Lord Denning, Master of the Rolls, was a driving force in the *Dutton* decision.

Within a short period, the *Dutton* decision was followed by the New Zealand Courts. In *Gabolinscy v Hamilton City*¹¹⁴ the council was found to be liable to the purchaser of a dwelling erected on a former council refuse tip, for subsidence damage occurring ten years after construction. The property foundations were not adequate for the ground conditions.

The validity of the common law in the U.K. came before the House of Lords in *Anns v Merton London Borough Council*¹¹⁵ being another case involving a claim for faulty foundations and subsidence damage. The Lords considered that on principle negligence liability should be approached in two stages. First, a question arose whether there was a sufficient relationship of proximity between the alleged wrongdoer and the person suffering damage, and secondly, if that proximity existed, it was necessary to consider whether or not there was a reason to exclude liability. This approach containing a presumption of liability advanced the scope of responsibility to a significant level where damage arose.

¹¹⁰ Until the Supreme Court Act 2003 (NZ), the Privy Council (UK) was the highest appellate body in the New Zealand judicial system. The Supreme Court of New Zealand replaced the Privy Council.

¹¹⁴ *Gabolinscy v Hamilton City* [1975] 1 NZLR 150.

¹¹⁵ *Anns v Merton London Borough Council* [1978] AC 728.

Returning to New Zealand, the *Anns* decision was followed by the Court of Appeal in *Mount Albert Borough Council v Johnson*.¹¹⁶ The Court considered the liability of a builder and the council in respect of a block of flats which had been erected on a former refuse tip site. The foundations were inadequate, the dwellings subsided, and the claim was made. The Court held the defendants were jointly and severally liable, and apportioned the damages award at 80 per cent against the builder and 20 per cent against the council. This ratio of apportionment has been commonly adopted in the later decisions. Where the builder is insolvent and recovery cannot be made, under the law the council may be liable to pay the full damages award, and to seek any remedy for recovery of the balance against the insolvent builder.

3 Divergence of New Zealand Law following Murphy decision

In 1984, the House of Lords in the *Peabody Donation Fund* case¹¹⁷ reconsidered the principled approach to liability enunciated in the *Anns* decision. The Peabody Group was developing a housing estate through a building firm and permits had been obtained from the Lambeth London Borough Council. An error was made in respect of the use of rigid drainage connections. The Lords declined to find any liability against the local authority holding that in determining whether or not a duty of care was incumbent, it was material to take into consideration whether it was just and reasonable that a duty should arise.¹¹⁸ Further, the Lords considered that as the loss was essentially economic, and not related to personal injury, that would be a ground for not imposing any duty of care.

Subsequently in *Murphy v Brentwood District Council*¹¹⁹, another claim relating to defective foundations and economic loss came before the House of Lords. On this occasion, the Lords determined that the loss was purely economic and the council owed no duty of care in exercise of its statutory building bylaw functions. A duty could only arise in respect of foreseeable harm in the nature of injury to health or safety. Furthermore, liability in torts should be established on an incremental basis, and the statements in the *Anns* decision were generally disapproved.

With this background, in 1994 the New Zealand Court of Appeal was faced with conflicting authorities in the case of *Invercargill City Council v Hamlin*.¹²⁰ A dwelling had been constructed in 1972 on a boggy site. The depth of foundations was approved by the council but found to be inadequate for the site conditions. Within a short period cracks appeared. Finally in 1989, with the doors sticking, a claim was brought against the local authority for negligence in approving the shallow foundations on the plans and also in failing to carry out proper supervision under the bylaws. The Court noted the differing views expressed by the House of Lords in the *Murphy* decision, as against the earlier *Anns* decision. Cooke P stated “While the disharmony may be regrettable, it is inevitable now that the Commonwealth jurisdictions have gone on their own paths without taking English decisions as the invariable starting point. The ideal of a uniform common law has proved as unobtainable as any ideal of a uniform civil law”.¹²¹ The Judge noted that New Zealand did not have any equivalent of the Latent Damage Act 1986 (U.K.), and

¹¹⁹ *Murphy v Brentwood District Council* [1991] 1 AC 398.

¹²⁰ *Invercargill City Council v Hamlin* [1994] 3 NZLR 513 (CA).

¹²¹ *Invercargill City Council v Hamlin* [1994] 3 NZLR 513 at 523.

in 1991, a longstop claim limitation of 10 years from the approval of plans or supervision by the local authority had been introduced for future claims. That particular limitation did not apply to the *Hamlin* facts where the claim was brought before the enactment of the statutory limitation.

Another member of the Court, Richardson J, stated there were six distinct and longstanding features of the New Zealand housing scene which justified a duty of care being owed by the local authorities. First was the high proportion of occupier-owned housing. The second reason was that much of the housing construction was undertaken by small scale cottage builders for individual purchasers and these builders may require some supervision. The third reason was the nature and extent of government support for private home ownership with provision of low interest loans. The fourth ground was the surge in house building construction. The fifth ground was the wider central and local government support for private home building, through model bylaws and close supervision. The sixth reason was that there has never been a common practice for new house buyers, to commission engineering and architectural examinations or surveys of the building or proposed building before purchase. The Judge summed up that the question of whether it was just and equitable for the local authority to be under a wider duty of care had to be considered against this background which was special to New Zealand.¹²² The Court held the duty of care could apply to pure economic loss and the council was liable for the cost of repairs. Because the building company had gone out of business and was insolvent, the council would be obliged to meet the full damages award.

That decision of the Court of Appeal then proceeded to the Privy Council.

In *Invercargill City Council v Hamlin*¹²³, the Privy Council was faced with a relatively unique situation as to whether it should follow the decision of the House of Lords in *Murphy*, or affirm the traditional approach asserted by the New Zealand Court of Appeal. In giving judgment, Lord Lloyd of Berwick, noted that 17 years had passed between the construction of the dwelling and the later determination that the subsidence problems were due to the inadequate foundations. His Lordship noted the change to New Zealand law in 1991 imposing a longstop on claims of this nature.¹²⁴ It was acknowledged that the New Zealand judges were in a better position to decide on the appropriate divergence of the common law. It was also acknowledged that as the loss was economic loss, that no loss occurred until the defect was discovered or was so obvious to a reasonable owner that they would take action. On the facts, the claim was not time barred applying the claim period of 6 years from discovery of the cause of action. This important decision, accepting that in New Zealand a local authority could be liable for negligence in issuing a building permit, and in any failure of the inspection duty, has remained the legal position, but with an exclusion of liability in respect of commercial premises.

4 Limitation Period for Claims

An aspect of several of the earlier claims was the significant time between the construction of the faulty dwelling, and the possible visibility of the damage from subsidence. In the case of *Askin v Knox*, a dwelling was built in 1963 over an old creek bed with approval of inadequate

¹²² *Invercargill City Council v Hamlin* [1994] 3 NZLR 513 at 524-525.

¹²³ *Invercargill City Council v Hamlin* [1996] 1 NZLR 513.

¹²⁴ Building Act 1991 (NZ), s 91.

foundations, and a successful claim was made against the council in 1986.¹²⁵ Similarly, in the *Hamlin* case, the claim was made 17 years after construction.

Following the *Askin* case, the variable bylaw standards applied by local authorities in respect of building permits, were replaced by a uniform building code for the whole country under the Building Act 1991. The existence of this Act was acknowledged in the *Hamlin* decisions, as being consistent with local authority liability for negligent inspections, and providing an assurance that the scope of liability would in time be capped by virtue of a longstop provision for all claims. Section 91 provided that in any proceedings arising from the construction, alteration, demolition of a building or the carrying out of supervisory functions, civil proceedings could not be brought against any person 10 years or more after the issue of the building consent or a building inspection or issue of a code compliance certificate upon completion. It may be noted that had that longstop applied in the earlier *Hamlin* action, the case could not have succeeded.

That longstop provision has remained part of the law, and has been repeated in the replacement Building Act 2004¹²⁶. The existence of that section can be taken as a statutory acknowledgment that civil proceedings are contemplated to be taken against a local authority, and this is a confirmation of the appropriateness of the *Hamlin* determination in the New Zealand context. Furthermore, under the Building Act 2004, a new provision imposes implied statutory warranties for building work in relation to household units.¹²⁷ A household unit is defined to mean a building or group of buildings that is used or intended to be used only or mainly for residential purposes and to be used exclusively as the home or residence of not more than one household but does not include a hostel, boarding house, or other specialised accommodation.¹²⁸

The implied warranties state that the building work will be carried out in a proper and competent manner, in accordance with the plans and specifications of the contract, and in accordance with the relevant building consent; the materials used will be suitable for the purpose and will be new unless otherwise stated; the building work will be carried out in accordance with applicable laws and standards; the work will be carried out with reasonable care and skill; and the household unit will be suitable for occupation on completion. The owner of the building or land may take proceedings for breach of the warranties as if the owner were a party to the original building contract, and no provision in an agreement may take away the benefit of the warranty.¹²⁹ No time limit applies to the warranties but it would be expected the normal 6 year limitation period would apply.¹³⁰

5 Local Authority Liability for Commercial Buildings

In *Three Meade Street Ltd v Rotorua District Council*¹³¹, the High Court was required to determine whether the council owed a duty of care to the purchaser of a motel which was found to have various construction defects in the building. Venning J considered the application of the

¹³⁰ Limitation Act 2010.

¹³¹ *Three Meade Street Ltd v Rotorua District Council* [2005] 1 NZLR 504.

Hamlin ruling and also the decisions in Australia, Canada, and in *Murphy v Brentwood District Council*. The judge concluded that although there may have been a proximity between the council and the defects in the building relating to inspections, there were policy considerations which determined that the council did not owe a duty of care in respect of ownership of a commercial building or work done on the building. The purchaser company should be able to protect itself by contractual arrangements with the developers, and in any purchase contract if being a subsequent owner. The Building Act should not be construed to give rise to any statutory cause of action. The council did not owe a duty of care to the shareholder of the ownership company.

The *Three Meade* decision came before the Court of Appeal in *Te Mata Properties Ltd v Hastings District Council*.¹³² In this case, the appellants were purchasers of two motels, and discovered that each suffered from the leaky building syndrome. The owner claimed against various parties including the district council for the cost of remedial works, the loss of value of the property, consequential losses and general damages. Allegations were made of negligence in granting the building permits, inspection of construction, and issue of certificating compliance. The Court of Appeal held that the earlier *Hamlin* decision did not extend beyond domestic dwellings and did not support the claim. A possible basis for liability could arise if health and safety issues had been pleaded, but the claim was for purely economic loss. The test of purpose of the building was the purpose stated in the building permit. Motels were not included as household units under the Building Act. Baragwanath J stated “So Parliament has treated owners of “household units” and “dwellinghouses” as deserving special treatment: protection in respect of building quality, privacy and procedures for dealing with leaky building claims.”¹³³

After traversing the earlier decisions going back to *Dutton, Anns*, Baragwanath J observed “There are obvious policy reasons for confining tort liability to home owners on account of the special and distinctive value of the home in any society as giving effect to the basic right to shelter”.¹³⁴ The Judge stated “I am satisfied at this stage there is no justification for extending the *Hamlin* cause of action, based as it is on economic loss, beyond the specific limits of private dwellings”.¹³⁵ The claim against the council was struck out.

In a subsequent decision *Queenstown Lakes District Council v Charterhall Trustees Ltd*¹³⁶, the issue concerned a chimney fault which caused a fire and damage to a luxury lodge. A claim was brought against the council for negligence in approval of the building plans and for failure of adequate inspection. On this occasion, a differently constituted Court of Appeal held the council did not owe a duty of care to the owner of a commercial building to prevent defects, including defects that affected the health and safety of occupants. Owners of commercial buildings were not vulnerable and dependent on councils to protect their interests but were able to engage their own advisers and manage risks through contractual arrangements. The claim was for financial loss. The Court held “In the result we accept ...the Building Act does not seek to protect the value of buildings, or income streams from them, for commercial investors.”¹³⁷ The Court noted

¹³² *Te Mata Properties Ltd v Hastings District Council* [2009] 1 NZLR 460 (CA).

again that the imposition of a duty of care in the context of commercial buildings had been rejected in the U.K. following *Murphy*.

The conclusion is clear, that the liability of local authorities does not extend to defects in non-residential buildings or to residential type properties established as a commercial venture such as hotels, guest houses and motels.

6 Leaky Home Liability

In the past decade in New Zealand, a major problem has arisen from the construction of buildings which suffer from the “leaky home syndrome”. This problem is distinct from the question of faulty or inadequate foundations, and relates to a combination of approval of inadequate building methods through the former Building Industry Authority under the Building Act 1991, together with design changes and poor workmanship. The major causes of the property leaks have been the use of untreated timber for structural framing, the use monolithic wall cladding systems, with both standards formerly being approved by the Building Industry Authority. A design trend by architects or property developers of dwellings with flat roofs, and no overhanging eaves, has further contributed to the problems with building leaks. In addition, poor workmanship in failing to install flashings around metal windows and other joinery, and widespread use of plastic sealants which break down, have resulted in ingress of water. Further design changes removing any air separation space between the building framing and outside cladding, partly due to insulation requirements, have exacerbated the rotting of wooden framing where water has penetrated the structure. The mould problems and costs of remediation of leaky homes has affected thousands of dwellings and other buildings, and has affected the health and wellbeing of many residents.¹³⁸

In principle, the question of liability of a local authority has been determined by the *Hamlin* decision, namely that a duty of care is owed in respect of residential properties in relation to building consents, inspections, and the issue of code compliance certificates. The liability of local authorities has been confirmed in two recent decisions by both the Court of Appeal and the Supreme Court. The decisions known as *Sunset Terraces* and *Byron Avenue*, involved the owners of two multi-unit developments which were affected by water tightness issues and suffered significant damage from water ingress.¹³⁹ The claims against the local authority, the North Shore City Council, were substantial, to the extent that claims against other parties and the apportionment of liability, including the building developers, architects and subcontractors, would not necessarily be met due to insolvency.

In the *Byron Avenue* case, involving a 14 unit block of residential apartments, the council carried out nearly 100 inspections of the property, but within 4 years, water ingress was occurring around windows and causing structural damage. The High Court had found the council had been

¹³⁸ In *North Shore City Council v Body Corporate 188529 [Sunset Terraces]* [2010] 3 NZLR 486 (CA), at [64], Baragwanath J refers to research that estimates that 80,000 houses built with monolithic cladding in the 1990s had leaked or would leak. The reference is to Howden-Chapman P, Bennett J, Siebers R (eds), *Do Damp and Mould Matter? Health Impacts of Leaky Homes* (Steele Roberts, Wellington, 2009).

¹³⁹ *North Shore City Council v Body Corporate 188529 (Sunset Terraces)*; *North Shore City Council v Body Corporate 189855 (Byron Avenue)* [2010] NZSC 158, [2011] 2 NZLR 289 (SC). Affirming *O'Hagen v Body Corporate 189855 (Byron Avenue)* [2010] 3 NZLR 445 (CA); *North Shore City Council v Body Corporate 188529 (Sunset Terraces)* [2010] 3 NZLR 486 (CA).

negligent in carrying out the inspections, and there was a need to repair and re-clad the units. The fact that some of the owners may not have obtained a “land information memorandum” from the council (prior to purchasing the unit) was not a bar to an individual claim, but could be relevant to a reduction in the award of say 25 per cent for contributory negligence. The Body Corporate would be treated as agent for the unit owners in respect of the common property, and could represent the owners in a collective action. In respect of *Sunset Terraces* case, the fact that the ownership structure of some property owners was through a company or trust would not affect the plaintiff’s right to claim for what were essentially economic losses. The Court of Appeal upheld the liability of the council.¹⁴⁰

On further appeal, the Supreme Court (in a judgment in December 2010) affirmed the divergence of New Zealand law in the *Hamlin* decision from the U.K. position. Elias CJ stated that she did “not consider it would be principled to introduce restrictions on the liability of territorial authorities according to the form of ownership, the type of residence, or the value of the building”.¹⁴¹ The council argued that the *Hamlin* decision should no longer apply, but the remaining four Judges of the Court stated “Hundreds, if not thousands, of people must in the meantime have relied upon the proposition that the 1991 Act had not affected the common law position. For this Court to defeat that reliance retrospectively by holding that the true position was otherwise would represent an inappropriate use of our ability to depart from a previous decision of the Privy Council”.¹⁴²

The Court further stated “The duty affirmed in *Hamlin* is, in any event, a soundly and firmly based principle of New Zealand law. There are good policy reasons for it.”¹⁴³ In response to a submission from the council that the duty should apply to single owner-occupied dwellings alone, and not multi-unit apartments that could be rented out to tenants, the Court stated “The duty affirmed in *Hamlin* is designed to protect the interest citizens have in their homes. As a matter of principle and logic that duty should extend to all homes, whatever form the home takes. Distinctions based on the ownership structure, size, configuration, value or other facets of premises intended to be used as a home are apt to produce arbitrary consequences. Furthermore the *Hamlin* duty must be capable of reasonably clear and consistent administration”.¹⁴⁴

The Court concluded “For these reasons we agree with the Court of Appeal that a building’s intended use, in accordance with the plans lodged with the council, is the most appropriate determinant of the scope of the *Hamlin* duty. Councils owe a duty of care, in their inspection role, to owners, both original and subsequent, of premises designed to be used as homes”.¹⁴⁵

¹⁴⁰ *O’Hagen v Body Corporate 189855 (Byron Avenue)* [2010] 3 NZLR 445 (CA); *North Shore City Council v Body Corporate 188529 (Sunset Terraces)* [2010] 3 NZLR 486 (CA).

¹⁴⁴ *North Shore City Council v Body Corporate 188529 (Sunset Terraces)*; *North Shore City Council v Body Corporate 189855 (Byron Avenue)* [2010] NZSC 158, [2011] 2 NZLR 289 (SC) at [49].

¹⁴⁵ *North Shore City Council v Body Corporate 188529 (Sunset Terraces)*; *North Shore City Council v Body Corporate 189855 (Byron Avenue)* [2010] NZSC 158, [2011] 2 NZLR 289 (SC) at [51]. The Court left open for later decisions application of the duties of care to particular premises.

The fact that with reference to the *Byron Avenue* building, the council had not issued a code compliance certificate, did not negate the duty of care in respect of acts and omissions prior to that point in time. The Court observed that the term “inspection” was defined under the former Building Act to mean “the taking of all reasonable steps to ensure that any building work is being done in accordance with the building permit”.¹⁴⁶

Regarding a liability issue that could arise where a claim had been brought and determined, and then the property had been sold, the Court considered a number of situations. The potential for an accrual bar was born out and reduced by the longstop 10 year limitation. It was held the duty owed to a first owner would not be transferred to the second owner on sale nor would the loss. The duty would be independently owed to the second owner and in principle that owner should be able to recover loss in respect to any breach of duty owed to that person independently of the first owner’s position.¹⁴⁷

Where there was a reasonable possibility of intermediate examination by a purchaser, the omission to carry out an inspection could be relevant to a question of contributory negligence or failure to mitigate, but would not defeat the claim. Further, the law provides for a prospective owner to request a land information memorandum (LIM report) from the local authority which could possibly include information as to the property being a leaky home. Where a report was not obtained in this situation, the failure to obtain the report could amount to contributory negligence and reduce the liability.¹⁴⁸ A council may be liable for negligent errors or omissions in the content of a LIM report.¹⁴⁹

In summary, the Court confirmed that the *Hamlin* decision was correctly made; councils owe a duty of care in their inspection role to owners, both original and subsequent, of premises designed to be used as homes; subsequent purchasers of such premises are not barred from claiming for breach of the duty owed to them solely by reason of a cause of action having accrued to a predecessor in title.

As noted, the duty of care is owed in respect of a property erected as a residential property or home (including a unit rented out or leased), but does not extend to a property erected for a commercial purpose, such as a hotel, motel, school, or industrial purpose.

7 Liability for Actions of Independent Certifiers

The former Building Act 1991 (repealed 2004) provided for developers a choice to use independent certifiers for approval of building plans, inspections, and the issue of a code compliance certificate. A limited number of private companies or persons were approved as certifiers for this purpose. A condition was that the certifier should have adequate insurance cover for public liability claims. The Building Industry Authority was empowered to approve

¹⁴⁶ *North Shore City Council v Body Corporate 188529 (Sunset Terraces); North Shore City Council v Body Corporate 189855 (Byron Avenue)* [2010] NZSC 158, [2011] 2 NZLR 289 (SC) at [62]. Building Act 1991, s 76(1)(a).

¹⁴⁷ *North Shore City Council v Body Corporate 188529 (Sunset Terraces); North Shore City Council v Body Corporate 189855 (Byron Avenue)* [2010] NZSC 158, [2011] 2 NZLR 289 (SC) at [72].

¹⁴⁸ *North Shore City Council v Body Corporate 188529 (Sunset Terraces); North Shore City Council v Body Corporate 189855 (Byron Avenue)* [2010] NZSC 158, [2011] 2 NZLR 289 (SC) at [76]-[84]. See also Local Government Official Information and Meetings Act 1987, s 44A (provision to obtain LIM report from council as to factors affecting a property).

¹⁴⁹ *Vining Realty Group Ltd v Moorhouse* [2010] NZCA 104 (error in recording water permit for rural property).

the use of the independent building certifiers, in place of a local authority. Where the certifier approved building plans, carried out the building inspections, and issued a code compliance certificate, the local authority had no discretion to reject the approvals.¹⁵⁰

In all cases where a local authority is the building consent body, involving a defective building or leaky home syndrome, the local authority would be one of the primary defendants, as the local authority would have sufficient resources to pay the full amount of any damages awarded. However, where a private certifier is involved in the whole approval and inspection process, the local authority has no legal liability or responsibility. That outcome has been upheld in the Court of Appeal. Consequently, where the certifier has gone into liquidation and the builder is also insolvent (being a not uncommon feature), a property owner may be unable to succeed on a claim or recover any damages awarded.¹⁵¹

8 Liability of Central Government (Crown)

Under the Building Act 1991, the Building Industry Authority was constituted with the function of making determinations on the accreditation of building products and processes, to the effect that where an accredited process was used, that standard would be the maximum standard required under the building code. Where the standard applied, a local authority was not entitled to impose a higher standard. The use of untreated pine timber for framing was part of an approval issued by the Building Industry Authority, together with the use of fixed faced monolithic cladding systems over the untreated timber. It became common ground from 1998 that this approval, given in 1995, was the basis of the growing leaky building syndrome complaints. Further, the approval of an independent certifier by the Building Industry Authority required the latter body to be satisfied that the certifier carried reasonable insurance cover in case of any liability.¹⁵² With this background, the liability of the Crown for the actions of the Building Industry Authority itself became important, especially in a situation where an independent certifier had been employed but was insolvent, and the builder might also be insolvent.

In *Attorney-General v Body Corporate 200200*¹⁵³ the body corporate representing the 153 unit owners of the Sacramento complex claimed damages against the Building Industry Authority, together with other defendants, for damages for repairs estimated at approximately \$20m (10m pounds). The Attorney-General, on behalf of the Crown and the Building Industry Authority moved to strike out the cause of action against the BIA. The Court of Appeal noted the background causes of the leaky building syndrome which applied to the Sacramento complex, and considered the issue of principle as to whether the BIA could owe a duty of care to the building owners in addition to a duty of care owed by the building certifier company. The Court determined that policy considerations pointed against a duty of care, namely that the roles of the BIA were of a quasi-judicial or legislative nature, and where building certifiers were involved

¹⁵⁰ Building Act 1991, ss 51-57. The system was a partial privatisation objective of the government. The Building Act 2004 has omitted the provision for private certifiers.

¹⁵¹ *Auckland City Council v McNamara* [2010] 3 NZLR 848 (local authority under no liability for actions of independent certifier). Independent certifiers had a minor share of the building consent process.

¹⁵² Building Act 1991, ss 7, 51, 56, 59.

¹⁵³ *Attorney-General v Body Corporate 200200* [2007] 1 NZLR 95 (CA) (Sacramento complex).

their certificates were conclusive.¹⁵⁴ Imposing a duty on the BIA would have significant resource implications for the BIA and its management of the Building Act 1991. The Court stated that maladministration by a public body was not in itself a ground for awarding damages. Importantly, proximity considerations pointed against any situation or duty to the building owner.

Likewise, the Court could not find that any duty of care would be owed to the building owner in the approval of a private building certifier, who subsequently went into liquidation and would be unable to meet any damages claim. The Court concluded that the relationship between the BIA and the building owners was extremely limited and matters of proximity and remoteness and causation were not able to be established. The claim against the BIA (and the Crown) was struck out.¹⁵⁵

In considering the justice of this decision, it may be noted that, having regard to the earlier decisions and criticisms of the inadequacies of the Building Act 1991, the government moved to reform the law and practice by enacting the comprehensive Building Act 2004.¹⁵⁶ The Building Industry Authority was disestablished and replaced by an approval system under a new Department of Building and Housing. The provision for independent certifiers was abolished. A system of licensed building practitioners is established to improve the quality of specified work.¹⁵⁷ Although the Crown is presently under no liability directly for the leaky home crisis, the Crown is offering a partial grant of up to 25 percent of repair costs (without any admission of liability) under pending legislation (considered below).¹⁵⁸

The present situation remains that the local authority will continue to be the building consent authority, and potentially liable for negligence in the approval of building plans, inspections, and issue of code compliance certificates, in respect of residential properties. Further, to the extent that in many claims the original architects, builders, subcontractors and other persons who may have a primary or secondary liability, may no longer be solvent or able to undertake remedial work, the local authority will be the “last man standing” and may be liable for the whole of the losses and damages established.

9 Weathertight Homes Resolution Services

Recognising the major and serious problems with the substantial number of leaky home claims arising, and the fact that ordinary household insurance policies do not usually cover losses arising from building deterioration or water ingress from normal rainfall, the government enacted the Weathertight Homes Resolution Services Act 2002. The Act established a process whereby a claim could be made to the Service for an assessment of the remediation costs, and for mediation

¹⁵⁴ *Attorney-General v Body Corporate 200200* [2007] 1 NZLR 95 (CA) at [62]-[69] .

¹⁵⁵ See also *Attorney-General v North Shore City Council* [2010] NZCA 324 (The Grange) (further claim by council of duty of care owed by BIA struck out).

¹⁵⁶ Hunn D, Bond I, Kernahan D, “Report of the review group on the weathertightness of buildings to the Building Industry Authority” 31 August 2002 (report critical of performance by BIA).

¹⁵⁷ The Building Act 2004, part 4 (system of licensed building practitioners to undertake or supervise specified works) .

¹⁵⁸ Weathertight Homes Resolution Services (Financial Assistance Package) Amendment Act 2011.

if possible of the liability. Due to the volume of claims and increasing complexity of issues, the Act was replaced in 2006.

The Weathertight Homes Resolution Services Act 2006 states the purpose, namely “The purpose of this Act is to provide owners of dwellinghouses that are leaky buildings with access to speedy, flexible, and cost-effective procedures for assessment and resolution of claims relating to those buildings”.¹⁵⁹

Several types of claim are stipulated. A dwellinghouse claim relates to a property built before 1 January 2012, and within a period of 10 years. The claimant must own the house and the claim can be brought where “water has penetrated it because of some aspect of its design, construction, or alteration, or of materials used in its construction or alteration; and the penetration of water has caused damage to it”. Provision is also made for claims in respect of single dwellings in a multi-unit complex, and a multi-unit complex, and common area only claims, in respect of a complex.¹⁶⁰

Provision is made for common representation in respect of multi-unit complexes. The procedures apply to a dwellinghouse which is leaking, and by definition, a dwellinghouse includes an apartment, flat, or unit and any attached garage or shed, but “does not include a hospital, hostel, hotel, motel, rest home, or other institution”.¹⁶¹

Where a dwellinghouse owner has an eligible claim, the Resolution Services will arrange for an assessment to be made of the extent of the claim and estimated cost of remediation of the damage.¹⁶² That assessment can then be taken to mediation with limited cost to the applicant. The mediators have powers to require other responsible parties to join in the procedure.¹⁶³

Where a settlement is reached, and the local authority is the consent authority, it will probably be required to contribute to the award, in a proportion in the vicinity of 20-30 per cent responsibility. Where other parties found to liable default, the local authority may be required to meet a greater share of the liability.

If mediation is not succesful, the parties may take the matter to the Weathertight Homes Tribunal for compulsory adjudication. The Tribunal has the powers of a court to act in an appropriate manner in finding responsibility and apportioning liability. The claim may be for any remedy available in a court of law, and may include a claim for general damages to cover mental distress. A determination can be the subject of an appeal to the High Court.¹⁶⁴

Local authorities (and their insurers) have continued to be concerned about assuming the principal financial burden for the ongoing liability under leaky homes claims. In 2010, after

¹⁵⁹ Weathertight Homes Resolution Services Act 2006, s 3. The WHRSA is administered by the Department of Building and Housing.

¹⁶⁰ Weathertight Homes Resolution Services Act 2006, ss 13-18.

¹⁶¹ Weathertight Homes Resolution Services Act 2006, s 8.

¹⁶² Weathertight Homes Resolution Services Act 2006, ss 31-51.

¹⁶³ Weathertight Homes Resolution Services Act 2006, ss 77-88.

¹⁶⁴ Weathertight Homes Resolution Services Act 2006, ss 57-76, 89-96, part 2, sch 3 (procedure). For lower value claims, the proceedings may minimise the use of lawyers. For an appeal, see *Findlay and Sandelin v Auckland City Council*, HC, Auckland CIV-2009-404-6497, 16 September 2010 (Ellis J) (damages apportioned 80:20 between builder and council – general damages of \$25,000 for mental distress, reduced to \$17,000 for contributory negligence).

consultation, the Government agreed, despite being not technically liable, to contribute towards claims by a qualifying claimant. The Weathertight Homes Resolution Services (Financial Assistance Package) Amendment Act 2011 provides that the Crown and the participating territorial authority will each provide 25 per cent direct payment for agreed repair costs. Where the territorial authority was not the consent authority but an independent certifier was used (pre 2004), the territorial authority will not be liable but the Crown will continue its offer of 25 per cent. If the home owner accepts the offer, the home owner must agree not to claim further against the territorial authority (or the Crown), but will be able to pursue legal action against other parties for the remaining 50 per cent of the remediation costs. Where the scheme applies, the third parties will not be able to claim back against the territorial authority for any additional contribution.¹⁶⁵

This Financial Assistance Package has been enacted into law in 2011. In effect, central government accepts a moral responsibility for part of the leaky home problem. An advantage to local authorities of a contribution agreement is that their share will be pegged to 25 per cent with no risk of paying a higher amount if other parties are liable but do not pay respective contributions. In relation to all real estate valuations and transactions, much greater awareness is acknowledged throughout the country as to the need to obtain checks before purchasing houses and apartments.

10 Conclusion and further research

The history of legal liability in New Zealand of local authorities in respect of defective properties illustrates the adaptability of the common law to local circumstances. The liability is limited to residential properties, and does not extend to commercial properties. A 10 year longstop for claims applies from the date of approvals and actions of local authorities. The recent offer by central government to provide up to 25 per cent contribution towards the repair costs of leaky homes, in conjunction with a matching offer from local authorities, is regarded by local authorities and the wider community as a reasonable outcome. In the longer term, further research to achieve improvements in design and building standards should reduce the scale of claims for defective residential premises. The demarcation for liability between a commercial building and a residential building remains problematic.

¹⁶⁵ Weathertight Homes Resolution Services (Financial Assistance Package) Amendment Act 2011. The Minister may, on behalf of the Crown, give a guarantee or indemnity for a loan to meet the balance of the repair costs, and may recover any debt arising.

Affordable housing in Portugal and São Paulo Municipality: Comparison of space standards and socio-economic indicators

Abstract:

This paper compares the space standards set for affordable housing in Portugal and in São Paulo Municipality (Brazil), and seeks explanations for differences in the socio-economic context of each territory. The Controlled Cost Housing (CCH) in Portugal and the housing built within the program My Home My Life (MHML) in São Paulo Municipality are studied. Three research questions are addressed: Which program has more demanding space standards? Which social-economic conditions explain the differences in space standards? How different space standards influence the users' satisfaction? To answer these questions, space standards, socio-economic indicators and the users' satisfaction are compared. Space standards compared the number and type of rooms, the internal floor area of dwellings, the size of rooms, and the size of furniture and equipment. The study has shown that space standards set for CCH are more demanding than those set for MHML program. For instance, a CCH dwelling has almost two times the gross area of a MHML dwelling with the same number of rooms. The housing deficit, the low income of poor households and the option to sell highly subsidized affordable housing are reasons that justify the low space standards in São Paulo Municipality when compared to Portugal. Although affordable houses are substantially smaller in São Paulo Municipality, the satisfaction level of dwellers with the size of dwellings is higher. Therefore, a direct link between space standards and users' satisfaction cannot be set. We conclude that different political options on how to provide housing to low income households directly influence the space standards set for dwellings.

Keywords:

Brazil, Portugal, affordable housing, space standards

1 Introduction

In Portugal and Brazil, it is generally accepted that the main goal of housing policy is to ensure decent housing for all households. This can be achieved by facilitating access to property, by providing access to a rented house or by ensuring minimum conditions of habitability in existing housing.

Both to enable access to property and to create a housing rental stock, the State may support the construction of housing, usually called affordable housing. Its main objective is to provide decent housing at affordable prices for low income households. Therefore, minimum parameters are set to ensure that dwellings have a quality level suitable to meet, at least, the basic needs of dwellers within the lifespan of the construction. Maximum parameters can also be set to guarantee that housing cost is compatible with the economic capacity of low income households, as well as to guarantee a good use of funds invested.

The general requirements for adequate or decent housing have been internationally accepted (UN-Habitat, 1996): it should provide a safe, healthy, comfortable and functional environment, at an affordable cost. However, the performance demanded for each requirement often varies from country to country according to the prevailing cultural, social, environmental, technological and economic conditions.

To ensure functionality, a dwelling shall be large enough to meet user's needs in terms of living, cooking, dining, sleeping, bathing and storing household goods. Space standards set the conditions to fulfil these objectives and usually specify the overall area, size and dimensions of rooms, ceiling height and layout of dwellings.

This paper compares space standards set for the construction of affordable housing in Portugal and in São Paulo Municipality, and seeks explanations for differences in the socio-economic context of each territory. The case studies consist of the *Controlled Cost Housing* (CCH), in Portugal, and the housing built within the program *My Home My Life* (MHML), in São Paulo Municipality. The three research questions addressed are as follows:

- 1) Which program has more demanding space standards?
- 2) Which social-economic conditions explain the differences in space standards?
- 3) How different space standards influence users' satisfaction?

The following section explains the research methodology and Section 3 describes the two case studies. Section 4 compares the socio-economic indicators and Section 5 presents the results of the comparison between space standards. The results are discussed in Section 6.

2 Research methodology

The study was developed according to the following methodology:

- 1) Identification of the problem and definition of concepts;

- 2) Characterization of case studies;
- 3) Comparison of socio-economic indicators;
- 4) Comparison of space standards set by building regulations;
- 5) Cross analysis of socio-economic indicators and space standards;
- 6) Summary of key findings and discussion of results.

3 Case studies

3.1 Controlled Cost Housing

In Portugal, affordable housing is called *Controlled Cost Housing*. The State supports financially the construction of CCH through the *Instituto da Habitação e da Reabilitação Urbana* (Housing and Urban Rehabilitation Institute). CCH can be promoted by municipalities, housing cooperatives or private companies.

The main objective of CCH is to optimize the relation between cost and quality: dwellings should meet the occupants' needs and have a reduced cost, which is assessed from a long term perspective (construction, use and maintenance) (Portugal, 1985).

When completed, CCH may be sold or rented. There are no limitations of income to households buying or renting CCH, but a sold dwelling is subject to special rules determining the conditions of transferability for a period of five years.

Figure 8. Cover of building regulations for CCH and photos of two developments
(Source: Imprensa-Nacional Casa da Moeda and Marluci Menezes)

The CCH construction program was created in 1983 (Portugal, 1983). Between 1984 and 2004, about 126,000 dwellings were built, with an average of 6,300 dwellings per year (Coelho, 2006). In later years, the construction of CCH decreased. In 2008, only 1,500 dwellings were completed (OHRU, 2009).

A CCH development shall comply with all the legislation applicable within the location where it is built and shall also comply with specific building regulations for CCH (Portugal, 1985; Portugal, 1997).

3.2 Program My Home My Life

In São Paulo Municipality, there are several programs to support the construction of affordable housing. The program "*My house my life*" was launched in 2009 by the Federal Government of Brazil. This program is run by *Caixa Econômica Federal* (Federal Bank) and the developments can be implemented by public or private bodies, or in partnership.

The MHML program aims to reduce the housing deficit in Brazil. The initial goal was to build one million houses, and therefore facilitate the access to housing for low income households. In 2010, the initial objective was increased to three million houses. The priority of this program is to provide houses for households earning no more than 3 minimum wages, but, within this program, houses for households with incomes not exceeding 10 minimum wages are also to be built (Brasil, 2009).

Figure 9. Promotion poster of MHML program and images of two developments (Source: CEF)

The MHML program supports the construction of new buildings. When completed, houses are sold to households listed by local governments. Households have to meet the requirements of the program to apply for a dwelling, including having an income within a certain range (Brasil, 2009).

A housing development built under the program MHML shall comply with all the legislation applicable within the location where it is built and shall also comply with additional conditions set by the program (ABNT, 2000; CEF, 2009a; CEF, 2009b).

4 Comparison of social-economic indicators

4.1 Population and territory

Although the total population of São Paulo Municipality and Portugal is similar, the territory is quite different. In São Paulo Municipality, almost all the population is concentrated in a vast urban area. The area occupied by the São Paulo Municipality is about sixty times smaller than that of the Portuguese territory, and therefore the population density is about sixty times higher. The rate of annual population growth is also higher in São Paulo (Table 1).

Table 1. Population and territory indicators
(Source: INE, 2002; INE, 2008; GESP, 2009b; INE, 2009; IBGE, 2009)

	Year	Portugal	São Paulo Municipality	
Population	2001/2000	10.36	10.43	millions of inhabitants
	2008	10.60	10.99	
Rate of annual population growth	2008	0.17	0.95	%
Number of families	2001/2000	3.65	3.13	millions of families
Size of the families	2001/2000	2.84	3.51	persons
Area of territory		92,094	1,509	sq km
Population density	2008	115	7,283	inhab. per sq km

4.2 Housing stock

In 2000/2001, the housing stock of São Paulo Municipality was about 55 % of the housing stock in Portugal. There was a small deficit of housing per family in São Paulo Municipality and a surplus in Portugal. The number of dwellings per 1000 inhabitants and the number of dwellings per family was higher in Portugal than in São Paulo Municipality. The housing tenure was very similar in both territories (Table 2).

Table 2. Housing stock indicators
(Source: INE, 2002; IBGE, 2009; GESP, 2009b)

	Year	Portugal	São Paulo Municipality	
Housing stock	2001/2000	5.02	3.39	millions of dwellings
Dwellings per 1000 inhabitants	2001/2000	485	286	dwellings
Dwellings per family	2001/2000	1.37	0.95	dwellings
Housing tenure:	2001/2000			
- owner occupied		75.7	69.4	%
- rented		20.8	21.6	%
- other		3.5	9.0	%

4.3 Housing demand

In 2000/2001, the housing deficit in São Paulo Municipality doubled the one in Portugal. The number of unoccupied dwellings in Portugal was 30 % higher than in São Paulo. In both territories, the unoccupied dwellings were enough to cope with the housing deficit, although they might not have the location or be suitable to meet the housing demand (Table 3). The housing deficit in São Paulo is probably undervalued given that the number of dwellings per family is less than 1 (see 4.2).

Table 3. Housing shortage
(Source: INE, 2002; Fundação João Pinheiro, 2005)

	Year	Portugal	São Paulo Municipality	
Housing deficit	2001/2000	100	203	thousands of dwellings
Unoccupied dwellings	2001/2000	543	420	thousands of dwellings

Also in 2000/2001, the main deficiency of the Portuguese housing stock was its poor maintenance condition (Guerra et al, 2007; INE, 2002). In São Paulo Municipality, the poor urban planning, the lack of urban infrastructures and overcrowded dwellings were the main deficiencies (Fundação João Pinheiro, 2005).

4.4 Housing price

The price per square meter in the MHML program is about 40 % of the same value in CCH. Due to differences in price per square meter and in the overall area of dwellings, the price of a two-bedroom MHML dwelling is about 20 % of the same dwelling in CCH. The prices for flats and single family houses are different in the MHML program (Table 4).

Table 4. Housing prices
(Source: Portugal, 1997; Portugal, 2008b; CEF, 2009a)

	Year	CCH	MHML		
			Flat	House	
Price of two bedroom dwellings	2009	102,102	20,124	18,576	€
Price per square meter	2009	1,201	479	531	€

4.5 Family income

The gross domestic product (GDP) per capita of São Paulo Municipality is approximately 74 % of the same value in Portugal. The minimum wage in the State of São Paulo is approximately 45 % of the same value in Portugal. The annual income of the 20 % of the population of São Paulo Municipality with lower income is 12.7 % of the same value in Portugal. The annual income of the 20 % of the population of São Paulo Municipality with a higher income is 68.9 % of same value in Portugal. The percentage of the population below the poverty line is not comparable since the threshold adopted in Portugal is 2.59 times higher than in Brazil (including São Paulo Municipality) (Table 5).

Table 5. Family income
(Source: PNUD, 2003; Portugal, 2008a; INE, 2008; INE, 2009; IBGE, 2009; GESP, 2009a)

	Year	Portugal	São Paulo Municipality	
Annual GDP per capita	2007	15,400	11,375	€
Monthly minimum wage	2009	450	195 to 211	€
Annual income per person:				
- average of 20 % of the population with lower income	2007	3,667	466	€
- average of 20 % of the population with higher income	2007	22,310	15,364	€
Poverty line	2007	406	73,48	€

4.6 Housing affordability

In the MHML program, the monthly mortgage is 10 % of the gross household income, with a minimum value of € 19.35. The amortization period is 10 years (Table 6).

In CCH, households can buy a dwelling with their own savings and/or obtain financing (a loan) from a financial institution. Each household negotiates the loan conditions and the monthly mortgage varies according to their options. Alternatively, a household can choose to rent a dwelling. In the Social Renting Regime, the rent is estimated based on the household income and composition. For households with an income below 3 minimum wages, the rent is less than 20 % of their income (Table 6).

Table 6. Mortgages
(Source: Portugal, 1993; CEF, 2009a)

	Portugal		São Paulo Municipality	
	Buying	Renting*		
Mortgage per monthly gross income	Varies	< 20	10	%
Amortization of housing price	100	–	From 12.5 to 39.8	%
Amortization period	Up to 45	–	10	years

* Household with an income below 3 times the minimum wage in Social Renting Regime

4.7 Housing satisfaction

To compare dwellers' satisfaction with affordable housing, two studies of post occupancy evaluation were used. The study for Portugal was carried out in 2004. Sixteen CCH developments comprising 1,283 dwellings, distributed by the Portuguese territory and representing different types of promoters, were assessed. Data on dwellers' satisfaction level was obtained by questionnaire. From the total of questionnaires placed in the post-boxes, 304 of them were received back (Menezes and Martins, 2005).

In São Paulo, there is still no information on dwellers' satisfaction with their homes from MCMV program, since this program started in March 2009. Therefore, the results of a post-occupancy evaluation study of a housing development with identical spatial characteristics were used. The Jardim São Luíz comprises 2,301 housing units, but to assess dwellers' satisfaction a sample of 81 dwellings was chosen. Data on dwellers' satisfaction was collected, in the second half of 1997, with questionnaires being conducted by students (Romero and Ornstein, 2003).

Both studies assess dwellers' satisfaction in a four level scale (i.e., completely satisfied, mostly satisfied, mostly dissatisfied, and completely dissatisfied). Among the several questions asked on dwellers' satisfaction, both questionnaires include a specific question about the satisfaction level with the size of the dwelling.

According to studies analysed, there are many similarities in the way dwellers of affordable housing in Portugal and in São Paulo assess the spatial characteristics of their dwellings. Dwellers positively evaluate the size of the dwelling as a whole and the organization of rooms. However, their assessment is negative for the size of the kitchen and service areas. The level of satisfaction with the size of the dwelling expressed by dwellers of affordable housing in São Paulo Municipality is higher than that expressed by dwellers of affordable housing in Portugal (Table 7).

Table 7. Dwellers' satisfaction
(Source: Menezes and Martins, 2005; Romero and Ornstein, 2003)

	Year	Portugal	Jardim São Luíz	
Dwellers' satisfaction with the size of the dwelling	1997/2004	2.62	3.12	1 to 4

5 Comparison of space standards

5.1 Number and type of rooms

The number of bedrooms of a dwelling is different between CCH and MHML programs. CCH dwellings can have from no bedroom up to five bedrooms (Portugal, 1951; Portugal, 1997). All MHML dwellings must have two bedrooms (CEF, 2009a). In both programs a dwelling must also have a kitchen, a living room and a bathroom.

5.2 Area of dwellings

Floor area of CCH dwellings must be within a range set by minimum and maximum parameters. The floor area of flats set in MHML program is 71 % of the minimum floor area and 61 % of the maximum floor area set for CCH. The gross area of flats set in MHML program is 63 % of the minimum gross area and 53 % of the maximum gross area set for CCH (Table 8). In MHML program, flats are slightly larger than single family houses because they cannot be enlarged.

Table 8. Area of two bedroom dwellings
(Source: Portugal, 1951; Portugal, 1997; CEF, 2009a)

CCH				MHML			
Floor area		Gross area		Floor area		Gross area	
Min.	Max.	Min.	Max.	House	Flat	House	Flat
52	61	67	79	32	37	35	42 m ²

Naturally, the dwelling floor area per occupant set in MHML program is also substantially less than that set for CCH (Table 9). This parameter is calculated by dividing the floor area of a dwelling by the maximum or probable number of occupants.

Table 9. Floor area per occupant for a two bedroom dwelling
(Source: Portugal, 1951; Portugal, 1997; CEF, 2009a)

CCH				MHML	
	Number of occupants	Min.	Max.	House	Flat
Maximum	4	13.0	15.3	8.0	9.3 m ²
Probable	3	17.3	20.3	10.7	12.3 m ²

For MHML program, the floor area per occupant is 8.0 or 10.7 square meters depending on the number of occupants. It is important to take into account that in dwellings with less than 8.0 square meters of floor space per occupant the prevalence of pathological situations tends to increase. In dwellings with 8.0 to 14.0 square meters of floor space per occupant, dwellers' satisfaction tends to be negative (Pedro, 1999).

Figure 3 and Figure 4 present two-bedroom flats and houses from CCH and MHML program. Plans are at the same scale. Figure 5 shows the furniture and equipment included in each dwelling. The standard physical and use dimensions of furniture and equipment are as defined in Figure 6.

5.3 Ceiling height

For most rooms, the minimum ceiling height set by MHML program is higher by 0.10 m or 0.20 m than that set for CCH (Table 10). This difference seems appropriate since it makes possible to partly compensate for the less floor area of rooms in MHML program and to obtain an internal volume that is not too low.

Table 10. Ceiling height of rooms
(Source: Portugal, 1951; ABNT 2000)

	Living room	Bedroom	Kitchen	Laundry	Bathroom	Circulation	Storage	
							A>2.5 m ²	A≤2.5 m ²
CCH	2.4	2.4	2.4	2.2	2.2	2.2	2.2	2.2 m

MHML	2.5	2.5	2.5	2.4	2.4	2.4	2.5	2.4	m
------	-----	-----	-----	-----	-----	-----	-----	-----	---

5.4

**S
i**

ze and area of rooms

The floor area of bedrooms in MHML program is 82 % of that set for CCH. The floor area of the living room, kitchen and laundry in MHML program is 60 % of that set for CCH. The floor area of the bathroom in MHML program is 44 % of that set for CCH. No area is set in MHML program for storage and circulation (Table 11).

Table 11. Floor area of rooms for two bedroom dwellings
(Source: Portugal, 1951; Portugal, 1997; Portugal, 2006;
ABNT, 2000; CEF, 2009a; CEF, 2009b)

	CCH	MHML	
Bedrooms	19.5	16.0	m ²
Living room, kitchen and laundry	24.0	14.4	m ²
Bathroom	5.0	2.2	m ²
Storage and circulation	7.5	–	m ²
Total	56.0	32.6	m²

5.5 Furniture and equipment

The furniture and equipment that must be possible to include in a dwelling of MHML program is less than the one that must be possible to include in CCH (Figure 5) (Portugal, 1951; Portugal, 1985; Portugal, 2006; MSP, 1992; ABNT, 2000; CEF, 2009).

The standard physical and use dimensions of furniture and equipment set for MHML program are the same as or smaller than those set for CCH (Figure 6) (Portugal, 1985; Pedro et al., 2006; Pedro et al., 2011; ABNT, 2000; CEF, 2002; CEF, 2009b). The most significant differences consist of the furniture for the living room and the clear floor space for the kitchen, bathroom and foyer. In CCH, the clear floor space is larger to ensure the accessibility of disabled persons. It should be pointed that previous studies concluded that standard size of furniture set for affordable housing in São Paulo Municipality were smaller than furniture for sale in shops (Boueri, 2008).

6 Conclusions and discussion

6.1 Results

Which program has more demanding space standards?

The space standards set for construction of CCH housing in Portugal are more demanding than those set for MHML Program in São Paulo Municipality.

Which social-economic conditions explain the differences in space standards?

Three main reasons explain the differences in space standards.

1. The housing deficit is still a problem in São Paulo Municipality, contrary to Portugal where there is a surplus. A greater demand for housing in São Paulo Municipality contributes to the acceptance of low space standards.
2. The income of poor population in São Paulo Municipality is substantially less than the income of poor population in Portugal. Therefore, low space standards of MHML program are a way to make the price of dwellings affordable for low income households in São Paulo Municipality.
3. The policy approach to provide housing to low income households is different. In MHML program, low income households buy highly subsidized housing. The non refundable investment of the Federal Government is more than half of the dwelling's price. In order to increase the number of households covered by MHML program, the cost of dwellings is minimized and, as a result, space standards are necessarily low. In Portugal, low income households may either buy or rent CCH. If households choose to rent affordable housing, the rent is estimated taking into account their income. Hence, the aim of affordable housing is to ensure adequate living conditions for dwellers throughout the lifespan of buildings.

How different space standards influence users' satisfaction?

Affordable housing in São Paulo Municipality has almost half the area of affordable housing in Portugal. However, according to studies analyzed, dwellers express a higher level of satisfaction with the size of dwellings in São Paulo Municipality. Therefore, a direct link between space standards and users' satisfaction cannot be set. The results suggest that dwellers of CCH in Portugal have higher expectations or different lifestyles than dwellers of affordable housing in São Paulo.

6.2 Discussion

The following paragraphs present an analysis of the relationship between space standards of MHML program and the main policy options for affordable housing in São Paulo Municipality.

1. The main aim of affordable housing policy is to ensure adequate housing for all households. Therefore, setting minimum requirements for housing should be based on a technical study of the occupants' physical, social and cultural characteristics. The following criteria should be used

with decreasing order: current population needs, foreseeable evolution in these needs and limitations determined by economic viability. In MHML program, it appears that political motivations and economic constraints led space standards to fall below the current population needs and their foreseeable evolution.

2. It is widely accepted that overcrowding can affect residents' mental and physical health (Wren et al., 2000; Sheridan, 2003; Carmona et al., 2010). The pressures arising from situations of overcrowding may lead to psychological distress, mental disorders and less ability to concentrate. Crowded conditions are also linked with increased interpersonal aggression, sexually deviant behaviour, as well as hygiene and accidents risks. Furthermore, cramped homes, which do not fulfil the occupants' needs, may lead to social cohesion issues (e.g. children who have no space at home to study and/or to play, hang around communal areas and housing estates) and to negative social behaviours (e.g. poor social control of children may give rise to violence and/or vandalism). These health and social problems have medium and long term costs for society. It can be argued that these costs may outweigh the additional public funding that would be needed to support the construction of better housing in MHML program.

3. Given the similarities between Portugal and São Paulo Municipality regarding how dwellings are used, the differences in space standards raise the following question: are space standards too demanding in Portugal or excessively lenient in São Paulo Municipality? To answer this question we should take into account that space standards specified for Portugal are similar to those set in several European countries, such as Spain and France (Pedro, 2009). Whereas the floor area per inhabitant set in MHML program is near the critical threshold below which the incidence of pathological conditions tends to increase. Therefore, we may argue that space standards set in MHML program only take into account the basic needs of present daily life.

4. MHML program sets the maximum selling price and the generic technical characteristics of housing (CEF, 2009a). The design of affordable housing in this program raises the challenge of finding solutions that, within the limit price, maximize the conditions offered to dwellers. Savings in construction costs could compensate for dwellings with larger areas. To reduce the construction costs various strategies can be adopted, such as: streamlining the design (e.g., minimize the water and sewage facilities), using more efficient construction procedures (e.g., modular dimensions and standardized components) or adopting more economical types of promotion (e.g., self built housing or evolutionary housing).

5. The booklet that sets the conditions for the application of MHML program includes, as an example, plans of a house and a flat. These examples can steer developers to pre-established solutions that are not adequate to the site conditions, population needs or local culture. For each development, a new design should be prepared taking into account the physical environment of the site and the social characteristics of the population. Beyond a proper integration, the research into new designs encourages diversity and innovation in architecture and construction.

6. A building has a long lifespan lasting in some cases for generations. It is not easy to foresee the change in users' needs. The flexibility of a dwelling facilitates its adaptation to the evolving occupants' needs, but strongly depends on its spatial characteristics. Very small dwellings have reduced flexibility. The space standards of MHML program only take into account the basic needs of present daily life. A desirable improvement in the quality of life of São Paulo's

population may mean that, in the short or medium-term, the dwellings presently being built will become obsolete.

7. MHML program defines the requirements to be met in dwellings. However, no requirements are set regarding the building and the neighbourhood, except for one specification about minimum distance between buildings. The urban plot is driven only by the spatial planning instruments applicable to the location, if any. Therefore, the quality of the urban plot may not be guaranteed.

8. In the MHML program, only two bedroom dwellings are planned to be built. This type of dwelling is adequate for a nuclear family with one child or two children, but it is not suitable for other types of families such as single persons, childless couples, families with more than two children and extended families. If dwellings fall short of households' needs, they tend to modify their environments in an attempt to minimize the shortcomings. These changes, when performed without the supervision of the authorities, may endanger the building's safety and compromise the building's image.

9. The Brazilian media reported that in several States of Brazil applicants interested in acquiring a dwelling within MHML program formed long queues at registration offices. According to some reports, some applicants spent the night in queues to ensure their position (Diário Popular, 2010). Other reports refer to queues with more than 1,500 applicants (Tribuna do Norte online, 2009). These reports prove the population's adherence to MHML program.

For households with an income not exceeding 3 times the minimum wage, the conditions to buy a dwelling within the MHML program are very attractive. The monthly mortgage is 10 % of the household income during an amortization period of 10 years. After this period, the household owns a dwelling having paid, depending on its income, between 13.3 % and 39.8 % of the property value. However, the MHML program requires a non refundable investment by the Federal Government of more than 60 % of the selling price of the building. Without enough return of the initial public investment it is difficult to have funds to continue building new developments. MHML program will probably fail to provide housing for all low income households, being thus debatable if it is a fair and efficient application of public resources.

10. Taking into account the previous paragraphs (indicated between brackets), the following improvements in MHML program were recommended (Pedro and Boueri, 2010):

- Increasing the total floor area of dwellings to include larger bedrooms, living room, and toilet, as well as to provide storage space (paragraphs 1, 2, 3);
- Counterbalancing the possible rise of dwellings cost, due to the increased area, with strategies to reduce the construction cost per square meter or the monthly mortgage (paragraph 4);
- Promoting and rewarding developments that achieve high quality and innovation (paragraph 5);
- Encouraging innovative spatial and construction solutions that are economic and adequate to the dwellers' needs (paragraph 6);

- Setting requirements on the quality of the neighbourhood that address parking spaces, accessibility, urban facilities and services, public spaces and green areas (paragraph 7);
- Enabling the construction of dwellings with one, two, three or four bedrooms and adjusting the program of each development to local needs (paragraph 8);
- Increasing the return on public investment with other economic models (e.g., subsidized rents, self built housing, evolutionary housing or by simply expanding the amortization period) (paragraph 9).

11. In view of constraints imposed by the MHML program, building houses rather than flats may be a better option. In houses, it is easier to design solutions that start with an initial core, where the essential functions take place, and evolve with the progressive addition of new rooms. Evolutionary housing may be a path towards building decent housing, adjusted to the dwellers' needs at a reasonable initial cost.

6.3 Limitations of the study

When analyzing the results it is important to consider the limitations of the methodology listed below.

1. Only space standards that apply to the dwelling were compared. There can be some compensation of space between the exterior and the interior of dwellings (e.g., the lack of enough leisure space within the dwelling may be counterbalanced by a large private outdoor space).
2. To compare the satisfaction level of dwellers, studies of post-occupancy evaluation of housing developments in Portugal and in São Paulo Municipality were used. The methodology used in both studies was identical, which enabled the comparison of results. In the study for Portugal sixteen developments were assessed. In the study for São Paulo Municipality only one development was assessed. This development is similar to other affordable housing developments in São Paulo Municipality, but results about the satisfaction level of dwellers may not be representative.
3. MHML program is meant to be applied in municipalities all over the Brazilian territory. The São Paulo Municipality has different characteristics from most other municipalities. Some inconsistencies detected in the regulatory framework governing MHML program in São Paulo Municipality may result from the specificity of the territory examined. The urban parameters of MHML program may be undefined due to the need of extending its implementation to the whole Brazilian territory.

6.4 Future developments

Only space standards were compared. To enable a more complete understanding of the quality level of affordable housing it is important to compare other requirements, such as safety, health and comfort.

Designers and developers of affordable housing have a practical knowledge resulting from designing, building and sometimes dealing with dwellers. It is important to know their opinion about space standards presently enforced in both territories.

Besides MHML program, other programs are being implemented in São Paulo Municipality to support the construction of affordable housing. As MHML program, these programs have manuals containing requirements or guidelines for housing developments (CDHU, 2008). The requirements for these programs may be compared to understand how the new MHML program situates in the affordable housing being constructed in São Paulo Municipality.

A comparison of the affordable housing in Portugal and Brazil is particularly interesting since both countries share a common language and culture. However, extending this comparison to other countries could contribute to put the findings in the context of a more comprehensive framework.

Abstract:

The new enforcement strategies in business operation have challenged the control by regulatory mechanism where it evidences the emergence of self-regulation as a new enforcement mechanism in doing business. This recent trend is seen as the response to the critics that bureaucracy and laws limit businesses' freedom and autonomy. Construction industry is also one of which that receive the imperative handling of self-regulation and one that manifests this, is the formulation of code of ethics for the contractors within this industry. Code of ethics for the contractors is viewed as crucial given that the level of disputes involving them in construction project are high and their profession is often tainted with the reputation of involving in unethical behaviours or at least highly seen as such by the community. However, the impact of implementation of the codes at times is debatable due to its self-regulatory status. This paper will discuss the code of ethics for the contractor as a mechanism for the self-regulation in the perspective of Malaysian construction industry with special reference to the practices of good ethics for the contractors as highlighted in Malaysian standard form of contracts.

Keywords:

self-regulation, construction, code of ethics, standard form of contracts, Malaysia.

1 Introduction

1.1 Background of study

It is generally accepted that self-regulation brings the benefit to various industries in terms of its flexibility in the mechanisms adopted by particular specific industries or associations. Nevertheless, some perceive it as only a myth and are sceptical on its enforcement (Mustapha Kamil, 2009). Construction industry, being very complex and integrated by many aspects and institutions; which is commonly subject to various disputes is seen to benefit a lot from this self-regulation approach if it is enforced efficiently. The business industries in most countries approach self-regulation voluntarily, even though under certain circumstances and methods, it is backed by legislative sanctions. This allows the industry to accommodate its own types and operation in preparing mechanism for self-regulation for example, the Code of Ethics. However,

as a result, the industry tends to be lackadaisical in its enforcement. Therefore, this paper is aimed to examine the Code of Ethics as a mechanism of self-regulation in Malaysian construction industry and determine what can be the legal pressures for the Code of Ethics to be enforced. Data analysis has been made by reviewing the contents of literature on self-regulation and code of ethics. Interview also has been performed to obtain practical insights of Code of Ethics enforcement. This study is hoped to pave the way for further researches regarding the Code's enforcement in Malaysian construction industry.

1.2 Construction Industry in Malaysia and Self-Regulation

Construction industry has become among the major concerns for Malaysia in recent decades. For example, in 2011, the Government has intensified Public-Private Partnership through implementation of several projects with the allocation of RM1 billion from the Facilitation Fund which amounted to GBP206 million. Such projects for example are construction of more highways, power plant in Kimanis, Sabah, health academic centre and facilities project such as International Islamic University Malaysia Teaching Hospital, Women and Children's Hospital and Integrated Health Research Institute Complex. Government's commitment in development is further observed in the implementation of growth corridors development such as Iskandar Malaysia, North Corridor Economic Region (NCER), East Coast Economic Region (ECER), Sarawak Corridor of Renewable Energy (SCORE) and Sabah Development Corridor (SDC). For the development expenditure of the corridors in the Midterm Review of the 9th Malaysian Plan, RM6 billion is provided in the 2009 Budget which amounted to GBP 1.2 billion. Major construction projects are involved to deliver these growth corridors. This is further accelerated in 2011 where RM850 million has been allocated for their infrastructure support which amounted to GBP175 million.

The move towards self-regulation in construction industry is treated as significant in Malaysia. The Malaysian Construction Industry Master Plan 2006-2015 (CIMP) developed seven strategic thrust envisioned to place the Malaysian construction industry as a world-class, innovative and knowledgeable global solution provider. The second strategic thrust of CIMP is to strengthen the construction industry image that had been criticised for many weaknesses such as abandonment of government projects, shoddy work, discriminatory awarding of contracts, not being environmentally-conscious and others (Construction Industry Development Board Malaysia.(2006).¹⁶⁶ Thus, self-regulation is recommended to achieve this thrust. Among the key initiatives are professional bodies and association self regulating, tightening the particular schemes and licences as well as establishing code of ethics by construction-related associations. Malaysia goes further by providing 'Strategic Recommendations For Improving Environmental Practices in Construction Industry'¹⁶⁷ and promotes self-regulation as one of its recommendation.

Various parties are involved in the construction industry. The owner (employer), the designer (design professional) and the contractor are the key players in a construction project. Meanwhile,

¹⁶⁶ Construction Industry Development Board Malaysia. (2006). *Construction Industry Master Plan 2006-2015*. Available from <http://www.cream.com.my/publications/cimp.pdf>. [Assessed 27 April 2010].

¹⁶⁷ Construction Industry Development Board Malaysia. (2007). *Strategic Recommendations For Environmental Practices in Construction Industry 2007*. Available from <http://www.cidb.gov.my/cidbweb/bin/information/HSE/Strategic%20v5.pdf>. [Assessed March 12 2009].

the authorities (regulators), subcontractors, material vendors and others are the supporting players.¹⁶⁸ These players are governed by various legislations, guidelines and policies for example the Town and Country Planning Act 1972, the Street, Drainage and Building Act 1974, the Uniform Building By-Laws 1984 and the Environment Quality Act 1974. An important institution, Construction Industry Development Board has been established under Malaysian Construction Industry Development Board Act 1994 (CIDB) whereby the Act establishes a Board to promote, stimulate, improve and expand the construction industry. Various tasks have been undertaken by this Board for instance, carrying out research, providing consultancy research, accrediting and registering the contractors (Natkunasingham I. et al, 1999). This Board is also responsible in regulating the conduct of the contractors by providing many seminars, trainings as well as developing Code of Ethics as guidance for the contractors.

Other important institutions are such as Malaysian Institute of Architects that controls, promotes and organizes in the matters of architecture, Board of Architects Malaysia which is a statutory authority responsible for the enforcement of the Architects Act 1967, Board of Engineers as well as the Board of Quantity Surveyor in Malaysia which operates similar functions. As the key players in the construction industry, these institutions play important role in promoting self-regulation by being given the tasks to develop schemes and incentives as well as various codes of ethics to increase construction performance.

2 Self-Regulation as a New Mode of Governance in Industries

The role of coercive and punitive methods found in regulatory mechanisms as the important enforcement system has attained a challenge by the wake of new enforcement strategies. Through regulatory method of governance, private individuals and businesses lose their freedom and autonomy to bureaucracy and laws. The development of globalization views the role that is being played by the market or private parties in rule making and its enforcement. This gradually shows the emergence of business entities at the place where it surpasses the legal and economic control by the government. Self-regulation is one of the evidence that proves this new trend.

The term of self-regulation is widely known to exist in various fields. Religion, philosophy, education, health, law, policy and corporate are among those fields that receive self-regulatory treatment thus, various definition can be found in accordance to each respective area. It literally means acting according to one's own volition and not as a response to an external constraint (Carver and Scheier, 2000). This meaning is also commonly used in psychology where self-regulation is an important area of human behavioral studies. On a more specific perspective, Ogun, (1999) interprets that the concept of self-regulation 'covers an infinite number of self-imposed behavioural standards, including those determined internally by the management of a firm'. It also can be determined as 'variety of attempts by corporations to establish rule-based constraints on behavior without direct coercive intervention of states or other external actors' (Graham and Woods, 2006). Meanwhile, Sorsa, (2010) establishes that self-regulation is a collaborative effort where it demands the collaboration between various industry partners at various levels as well as with other stakeholders. This is evident in the industry self-regulation

¹⁶⁸ Construction Industry Development Board Malaysia, (2007). *Guidelines for Implementing Environmental Management System in the Construction Industry 2007*. Available from [http://www.cidb.gov.my/cidbweb/bin/information/HSE/EMSCI FEBRUARY 2007.pdf](http://www.cidb.gov.my/cidbweb/bin/information/HSE/EMSCI%20FEBRUARY%202007.pdf). [Assessed March 12, 2009].

where it 'entails collective action by member firms to improve the reputation of the industry as a whole' (Lenox, 2006). Thus, to limit self-regulation meaning into a single, standard definition is definitely might not be possible. As a result, the concept of self-regulation itself becomes complex and diversified. Furthermore, its compliance may be subjective and vary according to particular approach in the industries or areas.

The types of self-regulation can be found in various approaches. Van den Heuvel, 1994 as cited in Van der Heidjen, 2007 for example, defines the types as follows. Firstly, pure self regulation where initiatives are left totally with the parties by the government which become neutral if no law has been offended. Secondly, substitute self-regulation where the government has right to legislate if public interest is insufficiently served even though parties have their own initiatives. Thirdly, conditioned self-regulation where the government sets conditions to the results despite leaving the initiatives with the interested parties and lastly, covenants or contracts where the government is the participant in setting rules of conduct.

Meanwhile, Price and Verhulst, 2000 as cited in Van der Heidjen, 2007 categorise its types into firstly, mandated self-regulation where the government defines the framework and requires the industry to formulate and enforce the norms. Secondly, sanctioned self-regulation where collective groups formulates the regulation that later subject to the government approval. Thirdly, the coerced self-regulation where a collective group itself formulates and imposes regulation due to the reaction on threats of statutorily imposed regulations by the government. Finally, voluntary self-regulation where there is no active state involved.

From the above definitions, it is observed that most types of self-regulation require the intervention of government legislation regardless of how and at what stage it is required. It is argued here that even in voluntary self-regulation, the enforcement also depends on the principles of general law as its background.

The emergence of self-regulation as a mode to govern the industries is due to many reasons as can be seen today. It can be legal, political, social and economic reasons for the industries to self-regulate. Mainly, it is due to the perceived shortcomings in the enforcement of legislation, seen by the industrial community as a barrier to efficacy. The rapid growth of global economy creates many emerging complex modes of transactions, administrations and leaves huge venues for disputes in the markets. Many are skeptical to the sufficiency and ability of the legal infrastructures to cope with these market explosions where for an instance, they are perceived as 'too-slow, cumbersome, and complicated (and hence too costly)...' (Hadfield, 2010, as cited in Sorsa, 2010). The expansion of companies' businesses globally especially in countries with a weaker regulatory systems also demands that the industries need to be governed with the private regulator's hand rather than 'old-fashioned' legal infrastructure. In some developing countries, self-regulatory chances put up by the government in their unwillingness to regulate, might become incentives for the multinational corporations that are attracted to their weak regulatory systems to invest in these countries. (Haufler, 2001 as cited in Graham and Woods, 2006). Thus, it is submitted here that self-regulation emerges in these countries, politically motivated in the need of changes in their economy as a mechanism for the country's growth.

Self-regulation also emerges as response from the industries to the pressure from the society members such as consumers, activists and NGO. (Graham and Woods, 2006). Strikes, boycotts

and campaigns adversarial to the companies which involve in particular unethical practices are commonplace. Hence, many standards, schemes, management systems or codes are being developed or complied with to avert criticisms by public.

Public regulations normally involve some lengthy process of formalities than private self-regulation. Thus, more time is involved, higher costs are required and more expenses as regard to the technicalities as well as expertise also need to be spent. In contrast, costs of formulation, preparation and enforcement within the self-regulation mechanisms are much lower since these activities are mostly centralized around the experts within the industries themselves. Williams, (2004) suggests that 'the emergence of self-regulatory regimes within selected industries is a rational response to external pressures in the marketplace and the broader societies in which firm operates'.

3 Self-Regulation and Code of Ethics for the Contractors

The construction industry has familiarly associated with the image of being "Dirty, Dangerous and Difficult".¹⁶⁹ Many problems have been associated with construction industry. For examples, according to the statistic released by the Ministry of Housing and Local Government, until 31 December 2009, the construction of 281 housing projects in the country were categorized as sick projects, involving 40,686 buyers meanwhile 148 projects were abandoned projects involving 31,824 buyers.¹⁷⁰ Meanwhile, a survey regarding how professional ethics including by the contractors impact on construction quality demonstrates that 'ethical standard in Malaysian construction industry is considered lower', while 'quality-related issues are found to have correlation with unethical conducts of the construction players'. (Abdul Rahman, et al 2010). It is thus pertinent to transform this perception in order to ensure the sustainability of construction industry and self-regulation is seen as significant in changing the way business is done. Obviously, it departs from the usual approach since through self-regulation, industry is more flexible in the enforcement frameworks within its own sphere.

Self-regulation can be enforced through various tools. Among them are the codes of conduct, reporting activities, environmental, social and sustainable management systems, certification schemes, CSR values, labelling schemes, transparency and disclosure guidelines as well as stakeholder engagement and dialogue and rating agencies. (Albareda, 2008). Reviews on the literature on the subject of code of ethics somewhat found out that in many occasions, the term of 'code of ethics' has been used interchangeably with or defined inclusively as 'code of conduct'. For example, Anon. (2003) refers corporate codes of behavior as 'corporate codes of ethics, corporate codes of conduct, or less frequently, as standards of a corporation'. Meanwhile, Langlois and Schlegelmilch, (1990) as cited in Mcdonald, (2009) describe that codes of ethics as 'a statement laying down corporate principles, ethics, rules of conduct, code of practice or company philosophy, concerning responsibilities to employees, shareholders, consumers, the environment and society' and they expand the discussion of 'code of ethics' to include ethical

¹⁶⁹ n 1 above.

¹⁷⁰ Ministry of Housing and Local Government, 2011. *Perangkaan Terpilih. Kementerian Perumahan dan Kerajaan Tempatan Sehingga 31 Disember 2009*. Available from http://www.kpkt.gov.my/kpkt/fileupload/perangkaan_terpilih/pt2009/Buku_Buletin_Perangkaan_Terpilih_KPKT_Sehingga_3112_09.pdf.

guidelines, ethical policy, codes of conduct and governance directions. Further, their study highlights the difference between corporate code of ethics and professional codes whereby the former affects within the particular organization and the latter works within members of a professional body.

To achieve second strategic thrust of Malaysian CIMP 2006-2015, namely through self-regulation in addressing construction problems, the Government is aware of the necessity to have a specific code of ethics for the contractors. Based on the resolution of the Forum on Integrity in the Construction Industry in September 2005, CIDB has been given the task to develop this code and the Code of Ethics for Contractors (The Code) became effective on 1 March 2008. It outlines six key principles regarding the contractor's ethical practices as below:

Principle 1 : Honesty in carrying out responsibilities.

Principle 2 : Compliance with the laws and regulations.

Principle 3 : Respect for individual and community

Principle 4 : Importance of quality, skills and standards.

Principle 5: Importance of safety and health.

Principle 6: Importance of environmental preservation.

The Code is accepted and adopted by all building contractors in Malaysia, whether local or foreign contractors, in accordance with the definitions in Act 520 (Construction Industry Development Board Act, 1994 whereby all contractors are obligated to abide by this Code of Ethics. (Clause 1.2 (i) and (ii), Code of Ethics For Contractors, 2009). The wordings in the Code itself are thus unclear as regard to its compliance and enforcement and it has to be studied further to look at these issues.

Stevens, (1994) illustrates that the intent behind an application of a corporate code of ethics can be determined based on the following issues such as the manner of how the codes are communicated to employees and the extent of how the code is enforced as well as the impact of violation. These can lead to the answer whether the intent is 'self-protection, an attempt at promoting ethical leadership or management of a public image'. In this study, review of several corporate codes of ethics studies has been made and it shows that most codes are having little information on the issue of how they are communicated in the companies. Meanwhile as regard to enforcement, it discloses that the degree of code's enforcement varies for these companies where some codes did not have enforcement and implications mechanism while the others do have them for examples, requirement to sign affidavit of compliance (Cressey and Moore, 1983 as cited in Stevens, 1994), termination on code's violation (Pitt and Groskaufmanis, 1990 as cited in Stevens, 1994) and even some minority are having discussion as to legal prosecution (Matthews, 1987 as cited in Stevens, 1994). Regarding this, Sandersen and Varner, (1984 as cited in Stevens, 1994) appeared to conclude that the codes of ethics in their study were not effective given the general and non-descriptive language in the code regarding enforcement.

This study can be explored in comparing the Malaysian code of ethics for the contractors where focus should be made to look on how the Code is applied and enforced against these construction companies. As mentioned above, all building contractors including foreign contractors under the definition in Act 520 are required to accept and adopt the Code under clause 1.2. However, it provides for the application in general as no wording such as 'shall' has been used. The Code also outlines all obligations by using the word 'must'. Nevertheless, there is nothing in the Code that provides for the implication in the event any violation arises albeit clause 1.2 (ii) that provides for the obligation of all contractors to abide by the Code. It also appears that no method of application is provided in the adoption of the Code. Thus it is not clear whether the construction companies have to adopt the Code in their policy framework or not for the purpose of application. Likewise, the Code also does not provide for the administrative procedures for the handling of any violation. In the absence of such provisions, it can be deemed that the compliance of the Code on its wordings is very much voluntary in nature. Based on the language of the Code regarding enforcement and application, it can be assumed that the Code is a collection of mere guiding principles for the contractors to ensure their ethical behaviours that have no binding effect.

To inculcate the ethical principles among contractors, CIDB in practice has nevertheless taken steps for examples, mandatorily requiring the contractors to attend integrity courses in applying or renewing licenses. Even though, there is no specific monitoring Board has been set up under the Code presently, however at internal level, an informal enforcement team will be put up by CIDB that functions to provide advices for the contractors if any unethical case has been reported against them. Practically, the contractors will normally alert on this step since they have the reputation to be taken care of with CIDB as their regulatory body. (Ahmad Mahyadin, personal communication, June 21, 2011). In addition, the registration of contractors is also subject to specific conditions that also include ethical aspects where the registration can be cancelled, suspended or revoked if they involve in any fraud or misrepresentation in obtaining the certification or fail to execute any work unreasonably.¹⁷¹ However, it is submitted that these ad-hoc based actions should be completed with a formal task-force enforcement mechanism.

4 Application of general law against the Code of Ethics

The above analysis shows that there is no mandatory requirement for the construction companies to implement the Code of Ethics as a self-regulatory mechanism for contractors. The question thus arises as to how does compliance to ethical practices could be safeguarded?

It is noted that self-regulation operates within the backdrop of the law. Therefore, it is necessary to examine construction contract as mechanism of ethics compliance in construction industry and some principles of general law to look at their applicability as background legal redress for non compliance of self-regulatory mechanisms. In fact, some ethical practices for the contractors have been found mandated but are scattered throughout various pieces of legal mechanism.

The rights and obligations of construction key players are guarded by the construction contract they entered into. To date, the main construction contracts applicable in Malaysia are Standard Forms such as Public Works Department 203A (PWD 203A) (Revised 2007) which is applicable

¹⁷¹ CIDB Malaysia, Contractor Registration Certificate.

to government projects and Persatuan Arkitek Malaysia (PAM) Contract 2006 which is applicable to the private projects. As the main tool that controls the relationship between these players which includes contractors, it should also be an important mandating mechanism for ethics implementation pertaining to contractors. Therefore, some important express and implied terms of the Standard Forms should be analysed.

4.1 Express terms in Standard Forms of Construction Contracts

4.1.1 Performance of the Contract.

There are many obligations of the contractors that reflect the required ethical practices. Nevertheless, there are some important obligations that must be carried out for example, in the PWD 203A where bills of quantities form part of the contract, clause 9.2 (a) provides that the contractor undertakes that it shall comply with all requirements, statutory or otherwise, regulating or relating to the conduct, trade, business or profession of a contractor, and the contractor shall be fully and solely liable for all costs incurred thereby. This clause is thus arguably refers to all requirements including the Code of Ethics which is not statutory that regulating the conduct of contractors. Based on this clause, any breach of Code of Ethics should be treated as breach of this contract.

In clause 10.1(b) of PWD 203A, it is provided that the contractor shall perform the works in a proper manner and in accordance with good management practice and to the best advantage of the Government and clause (d) provides among others that the performance shall be done with the exercise of professional judgment and practice, requisite skill, care and diligence.

PAM 2006 Contract also provides that the employer may determine the employment of the contractor if the contractor fails to proceed with the works regularly and diligently under clause 25.1(c). These in fact imply that the contractor shall take the responsibility and use the skill, care and diligence to exercise construction activities that is more responsible towards the stakeholders. These clauses are thus reflecting the principle 4 outlined by the Code of Ethics where the contractors must uphold quality, skills and standard in their works.

4.1.2 Compliance with the Law

The contractor also shall comply with the relevant laws. This is provided in clause 21.1 of PWD 203A whereby it states that the contractor shall comply with any law, regulation or by-law, or any order or directive issued by any public authority or public service company relating to the works or in the case of public authority or public service company, with those systems the same are or will be connected. Government also should be indemnified against all penalties and liabilities if the contractor breaches any such statutory requirements.

Similar obligation can be found in clause for of PAM 2006 Contract whereby clause 4.1 provides that the contractor shall comply with and submit all notices required by any laws, regulations, by-laws, terms and conditions of any appropriate authority and service provider in respect of the execution of the works and all temporary works. Meanwhile, PAM 2006 Contracts clearly by clause 4.4, places liability against the contractor to pay and indemnify the employer in respect of any fees, levies and charges including any penalties which may arise from the contractor's non-compliance with any law, regulations, by-laws, terms and conditions.

These obligations are in line with second principle of the Code of Ethics, namely compliance with the laws and regulations. There are many legislations or rules involved in the procedures and process of construction projects. For example, the Environmental Quality Act 1974 imposes prohibition and restriction on main pollution activities into a specific environmental medium. Here, it implies the ethical practices as required in sixth principle of the Code, whereby all contractors must preserve the environment in carrying out their works.

Regarding the workmen, the contractor also shall comply with the Employment Act 1955, Employee's Provident Fund Act 1951 and the Industrial Relations Act 1967. For instance, clause 17.1 of PWD 203A provides for duty of the contractor to register local employees that includes permanent resident workers under the Employees's Social Security Scheme in accordance with the Employee's Social Security Act 1969. In the default to comply this, the government or the superintending officer may withhold an amount from any money which would otherwise be due to the contractor and which in the opinion of the superintending officer will satisfy any claim for compensation by workmen that would have been borne by the scheme had the default was not occurred. The Government may also pay for such contributions which are due and unpaid and deduct it from the amount due to the contractor by the Government.

PAM 2006 Contract provides similar obligation in clause 19. Since foreign workers are allowed to be engaged in private projects unlike the government projects, it further provides for the duty of the contractor to take out and maintain insurance policy for these workers. These reflects the fifth principle of the Code where among others, 'the contractors must pay attention to the welfare of their workers on humanitarian grounds in all circumstances throughout the period of their services as required by law'.¹⁷²

4.2 Implied Terms in Construction Contracts

The implication of terms into contract is one of the important elements in contract law. In many occasions, courts are required to determine these by implying the terms into the contract necessary to give effect to the contract apart from its express terms. In *The Moorcock case (1899) 14 P.D. CA.*, Bowen LJ explained that the implication made was derived from the presumed intention of the parties, with the object of giving business efficacy to the transaction that should have been intended by the parties. The construction contract is similar to the other types of contract in its application of common law rules. Courts will imply terms in construction contract to make the contract works. This study submits that implied terms that applicable in construction contracts which underlie the notion of ethics are as follows:

4.2.1 Workmanship.

The contractor must use proper skill and care in carrying out his obligation under the contract, which means one of workmanlike standard. The workmanship exercised by the contractor is the ordinary skill and care that can be expected from a reasonably competent contractor. It has been suggested that this is a continuing duty during construction process, not only upon completion (Furst and Ramsey, 2001). Thus, as the ethical competent contractors, in performing the construction works, all measures should have been reasonably observed to ensure a socially safe built environment. Construction companies should ethically control and monitor many aspects in

¹⁷² CIDB, Code of Ethics for Contractors.

their works, for example construction waste management, where they need to professionally scheduled the minimization and recycle of waste program that affect the soil, water and air largely, especially in major projects. Those in fact are the ethical practices within the scope of contractors' works.

4.2.2 Duty of Good Faith

The application of the duty of good faith, has received different treatment in commercial world. The courts in England hardly acknowledge this duty but on the other hand, other common law countries such as Australia and New Zealand are willing to accept this duty while US recognizes it in contracting. Even though no unanimous definition of good faith has been upheld, nonetheless, the concepts such as fairness, honesty and reasonableness have been associated with the proposition to acknowledge the duty. There are three notions which embrace the doctrine of good faith as suggested by Sir Anthony Mason. Firstly, an obligation on the parties to co-operate in achieving the contractual objects (loyalty to the promise itself), compliance with honest standards of conduct and compliance with standards of conduct which are reasonable having regard to the interests of parties. (Peden, 2003). It is viewed that this duty can be strongly held as the basis for ethical compliance. Construction companies and the employers should be responsible, reasonable and honest in their works. They should govern their relationship ethically to give effect to win-win situation including to the other stakeholders. Good ethical governance thus is reflected through the duty of good faith owed by them towards each other.

4.3 Law Relating to Criminal Offences

In self-regulatory method, nothing should be tolerated if any law has been offended, for example as regard to corporate crime. Corporate crime is defined as 'the offences committed by corporate officials for their corporation and the offences of the corporation itself' (Clinard and Quinney, 1973 as cited in Shuan, ca 2011). As an example, it is an ethical practice that the contractors should be honest as provided by the Code, thus they have to abide by the rules of proper tendering process. In the event of non-compliance, this may trigger fraudulent and unfair transaction and if the contractors involve in unscrupulous acts that are against these rules, the criminal law can be used for example by using the Penal Code.¹⁷³ If any issue of bribery is involved, then anti-corruption legislations could also be invoked.¹⁷⁴ This shows that the autonomy given to the self-regulation is always safeguarded by the laws, particularly if it involves serious breach or misconduct.

5 Conclusion

It is obvious that where the Code comprises a broader context of stakeholders where ethical practices should be upheld, the construction contract merely binds and covers the parties in the contract. Therefore, problem will arise where unethical practices are being complained against

¹⁷³ Under Malaysian Penal Code (Act 574) Cheating is provided under section 415 :Whoever by deceiving any person, whether or not such deception was the sole or main inducement,—(a) fraudulently or dishonestly induces the person so deceived to deliver any property to any person, or to consent that any person shall retain any property; or (b) intentionally induces the person so deceived to do or omit to do anything which he would not do or omit to do if he were not so deceived and which act or omission causes or is likely to cause damage or harm to any person in body, mind, reputation, or property, is said to "cheat".

¹⁷⁴ Anti Corruption Act 1997 (Act 575) provides for anti-corruption offences including bribery.

the contractors by parties outside the contract (Ahmad Mahyadin, personal communication, June 21, 2011).

Tay, (2009) views that implementation of code of ethics should be made compulsory for the companies where instead of being mere guidance, it should be made rules to follow. Meanwhile, Jenkins, (2001) views that to have real impact, it is significant that provisions should be made for the implementation of a particular code and effective monitoring. In addition, there is a suggestion by Judge Thornton that relevant parts of ethical code of Society of Construction Law, UK could be incorporated into among others, standard forms of contract (Uff, 2005). Comparatively, code of ethics for the contractors should be made compulsory for the construction companies to implement. It can also be part of our Standard Form of Contract. This can ensure that the Code does not serve as a mere window-dressing. It is also viewed that the Code can play the role as an important tool for self-regulation in construction industry, but needs to be mandated. Additionally, it is argued that even though no mandatory requirement has been provided regarding the Code, application of general law comes in hand to safeguard the compliance of ethical practices among contractors. However, to secure effective compliance, express provision mandating it should be in place.

The debates regarding the mandatory and voluntary nature of implementation of ethics in construction industry might never ends. The types of self-regulation as discussed above also illustrate that intervention of government regulation is required regardless of how and at what stage it is needed. Even for the voluntary self-regulation, the enforcement should also depend on the principles of general law as its background. The advantages of having mandatory ethical practices in fact are beyond doubt. By having these mandated, the construction companies will have ethical obligations to preserve and liabilities to answer. Even if Code of Ethics is practiced by construction companies, lackadaisical enforcement is expected due to its voluntary nature. Thus, it is possible to examine the situation in the construction contracts since the contracts govern the relationship between the construction players. It is submitted that clauses in construction contracts regarding the performance and compliance of law by the contractor as well as the implied terms of workmanship and good faith are the basis of ethics in the construction contracts, thus placing ethics on the mandatory nature in these contracts. However, this is insufficient as other stakeholders outside the contract will not be safeguarded against unethical practices of contractors. This study is limited in its scope to look at the impact of the Code of Ethics for the Malaysian contractors. In a nutshell, emphasis should be given to extend future researches on how this Code is adopted, communicated and complied within the construction companies since they involve complex issues that provide prolific grounds for discussions. It seems that in near future, this self-regulatory mechanism should not be treated as a mere catalyst in its functions anymore but rather the weaponry substance for the construction businesses to succeed in their 'business battlefield'.

Steps taken by CIDB for unethical practices complained against the contractor despite no specific monitoring board according to Mohd Nazli Ahmad Mahyadin (personal communication, June 21, 2011).

En route to a knowledge based Building Regulation and Control that interlinks societal requirements, scientific knowledge, education and building practice

Nico P.M. Scholten PhD¹

¹Expertcentre Regulations in Building ERB
Delft 2623 CR, The Netherlands

Email: n.scholten@bouwregelwerk.org

Abstract:

The regulatory system in the Netherlands was one of the first performance based systems. Successful as it was, there are still many problems with its practical application. Research by the Dutch ERB indicates that most of these can be attributed to a poorly functioning knowledge system in which regulations should be embedded.

Building regulations can be considered as a manifestation of knowledge and political decisions that enable practitioners to design and build such that minimal key societal needs will be met. It enables also owners and users to demonstrate that in the existing stock minimal key requirements are fulfilled. They are part of a knowledge cycle that involves all actors in the construction value chain. The actual goal of regulations is essentially to protect the public (general) interests of the end user and/or final owner. The end user / owner, however not part of the system, is remarkably enough legally liable in the case of default.

With this understanding as a basis, it is possible to reconsider structure and content of the regulatory system. Instead of being a tool for disputes, it should be a purposeful tool for actors in the construction value chain. This paper presents an innovative approach to the regulatory system. It comprises three levels for plan evaluation or judging of existing works. Processes and responsibilities are reconsidered, as well as education and roles of actors. The envisioned new approach stipulates better and more economical buildings, avoidance of unnecessary summons, and substantial cost savings in control.

Keywords:

building regulations, enforcement, knowledge system

1 Introduction

The Dutch Building Decree has been under discussion for decades. Excellent building rules and regulations form an important, even an essential link between building practice and society, aiming primarily at the availability of safe, healthy, usable and sustainable buildings. How effective building rules and regulations are, depends largely on their practical applicability, costs and the extent in which they provide for building innovations.

With its Building Decree 1992 Dutch legislation took an important first step en route to renewal of the system. As opposed to the traditional building regulations, the Building Decree does not prescribe in detail how to build, but indicates, by means of performance requirements, which objectives a construction or construction unit will have to meet. This system leaves space for the application of fresh, innovative solutions.

Now, almost twenty years later, it is time to evaluate the concept. Although the Building Decree has emerged to be successful in many aspects, various problems have also been noted which appear to be structural in origin.

The Expertisecentrum Regelgeving Bouw (Expert centre Regulations in Building-ERB) published its first, overall analysis in 2008 (Scholten *et al.*, 2008). One of its conclusions was that the end user – who, as the owner of a building, is legally accountable for it to meet the rules and regulations set – is represented too feebly in the building process, and often does not even play any role at all in the decision-making. Because of this, the end user could become the loser. As a result ERB assigned a group of experts and scientists to further investigate this issue and to come with a solution to this undesirable situation.

Other conclusions were that in the public and private sectors two separate courses of knowledge development took place, and that the building regulations in their present form insufficiently warrant that societal objectives are realised.

2 The present system

As a reaction to the abominably bad housing of city immigrants in the second half of the 19th century The Netherlands created the Housing Act in 1901. From then on the municipalities were responsible for the drawing up and enforcement of regulations in the form of local building codes. In the 20s and 30s of the 20th century, the Housing Act advanced the construction of good - and still attractive - dwellings.

After World War II building contractors began to operate more and more nationwide. They were confronted by masses of different and inconsistent local regulations. In order to be able to rationalise the building process, countrywide uniformity was required. In the first instance the answer were the Modelbouwverordening (the Model Building Bylaw), issued by the Vereniging Nederlandse Gemeenten (the Association of Dutch Municipalities). Because many municipalities stuck to their own building regulations, the call for countrywide uniform legislation became increasingly louder.

In 1982 the Lubbers-1 cabinet took the initiative that finally resulted in the 1992 Building Decree. The Housing Act determined that from then on municipalities, fire brigades and utility companies were no longer allowed to issue regulations supplementary to or deviating from the Building Decree.

This first Building Decree had a completely different structure of directives from what people were used to. In the old system, the building regulations described specific solutions to many regularly occurring construction problems; innovative solutions were not allowed. As the

Building Decree starts from the performance, required of complete buildings, constructors could from then on apply both standard and new, equivalent – or better - solutions.

Between 1992 and 1998 the government worked on the second round of the Building Decree which was never enforced. In the year 2003, the presentation form of the Building Decree was changed at the request of the market: the so-called table's legislation. However, the Dutch government simultaneously introduced a new modelling principle of works which did not link up with the experience of either the construction partners or citizens.

Since its publication in 1991, the Building Decree has been changed 29 times.

The Building Decree does not cover the whole spectrum of regulations relevant to building. For fire safe use the Decree on fire safe use of structures holds. For the demolition and the use of a building, municipalities still determine the contents of the regulations by local building bylaw. For specific buildings and safe and healthy work, specialised ministries published their own technical regulations.

Besides these, EU regulations for construction products were introduced, due to the free movement of goods.

In order to reduce the burden of too many regulations and organisational fragmentation the Dutch government recently decided to opt for four important measures:

- (a) one 'environmental counter' for the dealing with 'environmental' related permits (the Wabo = General Physical Environmental Rights Act).
- (b) bundle any knowledge at the enforcement level by combining the responsible local services at regional level; on the advice of the Mans Committee (Report Committee Mans, 2008).
- (c) organise the fire departments regionally (Wet op de veiligheidsregio's = Act on Safety Regions).
- (d) skip 25 per cent of the content of the Building Decree, 'deregulation', and combine: the Building Decree 2003, the Decree on fire safe use of structures, the demolition regulations and other works relates regulations of the building bylaws and the Besluit aanvullende regels veiligheid wegtunnels (BARVW) = supplementary rules and regulations on the safety of tunnels, in the Building Decree 2012; intended to become in force on January 1st, 2012. The Dekker Committee (2008) advised to research whether - a substantial part of - preventive public enforcement of the building regulations could be evaded in case the private sector would take responsibility for compliance (Report Committee Dekker, 2008)

3 A necessary review of the system

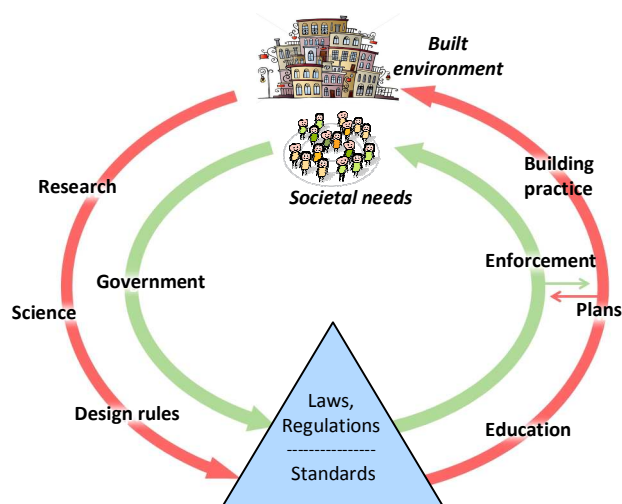

The four recent measures are administrative and organisational answers to problems that are rooted deeper. Both, the public legislation and privately developed system of Standards form part of a knowledge system we need in order to realise and manage safe, healthy and sustainable

buildings. That system must therefore function properly, which is not the case at present. Regulation becomes the more effective, the better it complies with this knowledge system. In other words: everybody involved in building and its management, must be able to properly understand, interpret and apply the regulations.

This knowledge should also lead to possible adaptations and the development of new regulations. Of course, these regulations should comply with the practice of design, construction and use. Lessons from practice should in turn lead to research and improved regulation. So, attention must be paid to the transfer of knowledge as well as to the restructuring of the regulations and the way in which regulation is affected.

3.1 The cycle of knowledge

The skill of designing and constructing good and reliable buildings is rooted in building science. This in its turn has largely developed empirically and is continually developed further. With a view to practical applications, scientific knowledge has been incorporated in design regulations, governmental rules and regulations and Standards. We may assume that buildings are sufficiently safe, healthy and sustainable when architects adhere to these regulations. Naturally, the same holds good for owners and users when managing and running their real estate. Should they not do so, we ought to change the regulations or stimulate people's adherence to the regulations. Occasionally, or in case of technological innovations, people should be able to deviate from the details in the regulations without necessarily endangering safety, health or sustainability. We have depicted the process outlined here as a circle of knowledge (see figure 1):

The *public* learning track (green): societal requirements are translated into rules and regulations through legislation, enforced according to public law by means of a licensing system, general terms and conditions, or sanctions recorded in the Housing Act, *Gemeentewet* (Municipalities Act) and the *Algemene wet Bestuursrecht* (provisions of administrative law);

The *private* learning track (red) runs from research and science, through technical specifications and known solutions which are transferred in training programs, leading to professional practice. Some of these specifications and agreements have been laid down in Standards and assessment guidelines.

Figure 1. Knowledge circle
(Source: Scholten *et al.*, 2010)

Building regulations combine the two tracks to become a crossroads. Knowledge of Standards and their background is also essential for enforcement, and knowledge of rules and regulations is

just as important for education and training programs. On the basis of the ideal model we are able to clearly illustrate the practice related hitches.

Figure 2 charts these hitches.

Figure 2. Hitches in the knowledge circle
(Source: Scholten et al, 2010)

The first general problem is that the various actors in the private-law circle of learning work totally independently from each other. Universities, research institutes, schools for professional training, commissioning clients, designers, engineering consultants, building contractors, fitters, suppliers and consumer representatives, they all adhere their own policies, focusing specifically on their direct self-interests, and without much mutual coherence.

The next problem is caused by both a highly fragmented sector and the fact that not a single party individually obtains a competitive advantage from investing in the development of communication systems and therefore does not do so, however these systems are necessary to structure and improve mutual understanding in such a fragmented sector. Centralised communication systems are no-one's priority, and no 'central market superintendent' exists who could organise this.

And then there are other factors. We refer to the characters in the black circles of figure 2.

In order to make public-law rules and regulations and private-law agreements match, the two learning tracks on the left-hand side should be linked up with each other. At present there is no interaction whatsoever.

Standardisation must be based on research. The performance requirements must be based on measurement, determination or calculation methods. At present, unfortunately, many terms and conditions, and Standards are insufficiently founded by science. Due to the lack of proper financing, universities have little interest in the methodology and modeling necessary to formulate rules and regulations. The large technological institutions such as TNO (Netherlands Organization for Applied Scientific Research) largely depend on occasional commissions from the government and industries. This is the reason why they miss the long-term stamina necessary for the development of scientifically sound rules and regulations or Standards.

The knowledge on which the development of regulations and Standards is based has been insufficiently recorded and managed in the present system. After the successful completion of a regulatory project, everybody should be able to easily find the relevant background information with a view to an unambiguous interpretation, and support of the equivalence of possible, fresh solutions. Now, this knowledge seems to ebb away to such an extent that even the responsible bodies themselves do not always understand their regulations.

Individual private-law regulations, such as Standards, have been drawn up based on different disciplinary backgrounds, for instance: by constructors, experts in fire safety, and those in building physics or materials specialists; so these regulations do not match nicely. One result is a differing and inconsistent use of language. As the Building Decree (2003) refers to such regulations, unavoidable inconsistencies develop in legislation. The legislator's language use is not that of the standardisation commissions, while neither speak the language of the man on the building site (shop floor). The performance approach requires a level of abstract thinking which is not used on the shop floor; specialists with secondary education only understand problems by means of practical solutions. Would regulation be consistent and in shop floor language, the correct application of regulations would improve greatly.

The scope of application of building regulations should probably be extended. According to the original Housing Act, building rules and regulations were meant for the safety and health of the users of a building. Later, as an effect of these, regulations were added with a view to its usability and energy efficiency, later followed by accessibility and sustainability. Up to now, economic and cultural aspects and the prevention of criminality have been included only to a small degree. However, the regulations which have to promote the well-being of construction and aid-workers, such as firemen, have been laid down in the *Arbowet* (Law on Conditions at the Workplace); one can only find them implicitly in building regulations. Although the construction industry is one of the most dangerous, unhealthy and energy-consuming economic sectors. Presently, the building regulations pay very little attention to maintenance, renovation, and demolition. Surely, a building application or process should not only meet the building regulations, but also satisfy the *Warenwet*, (the Commodities Act: elevators and appliances), the *Wet milieubeheer* (Environmental Management Act), the *Kernenergiewet* (Nuclear Power Act: ionisation alarm), *Politiewet* (Police Act), *Archiefwet* (Records Act) and the Law on Conditions at the Workplace. With such complexity it is not surprising that people experience regulations related stress.

Rules and regulations only form a minor part of the curricula in secondary and tertiary professional education and universities. This creates an important lacuna in knowledge both within industries and law enforcement organizations of the government. It seems as if people no

longer see how closely the administrative and building laws as well as technical regulations are connected.

Preventive assessment governed by public law is done only on the design stage of a building. So, one cannot even be sure that buildings realized actually comply with the relevant regulations.

In today's building processes the end user, often the owner (to be) of a building, hardly plays a role. As the end users often are parties differing from the commissioners of buildings, their individual interests will generally be insufficiently represented according to private-law in the design and construction stages, so they will have to be able to rely on the public rules and regulations to sufficiently protect their interests. Many commissioners completely ignore all kinds of aspects that, for a society, are desirable and beneficial in the long run – think of the accessibility of buildings for persons with functional limitations, or the adaptability to various purposes of a building. If these requirements have been carefully dealt with in their design and construction, the layout of buildings will need to be converted less often, they will have a lower risk of vacancy, and early demolition due to their being unfit for purpose, will be their fate less often. The only way in which to realise this societal interest is for the government to list minimum regulations and enforce them.

4 A suggestion for improvement

Starting point is the enforcement of regulations whose societal usefulness have been proven. To diminish the burden of overregulation we can classify building plans on three different levels of argumentation per assessment aspect.

A first level is meant for easy assessment of 'standard solutions'. We assume that possibly 80% of the building plans or existing buildings are or consist mainly of 'standard solutions'.

The middle level more or less resembles the present Building Decree 2003 that focuses on performance.

The third level we propose, concerns building works in which unconventional and innovative solutions are to be implemented, using a probabilistic approach.

Should an applicant and the law enforcement organisation differ in opinion on whether a proposal meets the level of the standard solutions or the level of the ordinary assessment according to the performance requirements of the Building Decree, the third level would then provide the possibility of assessment according to the societal objectives regarding safety, health, usefulness, energy efficiency and sustainability. In that way discussions as regards technical content need not end in legal disputes.

For many people the introduction of these two new levels will substantially diminish the overregulation burden. At the levels of building and standard solutions assessment of the existing stock, one could then implement the greatly simplified regulations instead of those of the Building Decree 2003. While, at the third level, one can judge innovations according to societal objectives which present regulation does not provide for.

It is in no-one's interest to enforce regulations that are understood insufficiently. The supplements suggested greatly increase the practical usefulness of the regulations and they enhance the legislator's actual objective - the enforcement of safety, health, usefulness, energy efficiency and sustainability. That is why regulation is linked with objectives. The guarding of different, but coherent, assessment levels can thus be solved methodically.

We propose also to improve the process of securing regulation related knowledge. Assessment of building plans by local authorities contributes far too little to this end. Together with all those involved in the building process - from science, knowledge institutes, education, architects and engineering consultants, to and including the actual builders and the real estate sector - we must try and form a secure chain of knowledge with properly linked up sub processes. Only with a properly functioning knowledge system can we rely on the building sector to realise of its own accord the societal objectives which we may expect from it.

Procedural innovations are required. We need to attune the three assessment levels. The accepted standard solutions will be assessed according to the performance requirements as laid down in the second category and the question whether the performance requirements themselves meet the objectives set, is answered by means of the risks approach which we will apply in the third category.

The elements which the three levels have in common, we have to establish at a generic level: objectives, risks models, user models, functional models and performance requirements.

The general structure of rules and regulations as presented below, in figure 3, has been depicted in the form of a grey triangle. This part of the structure ensures that the system remains consistent, also when societal objectives change and renewals are introduced. The parts relevant to applicants and assessors are in blue.

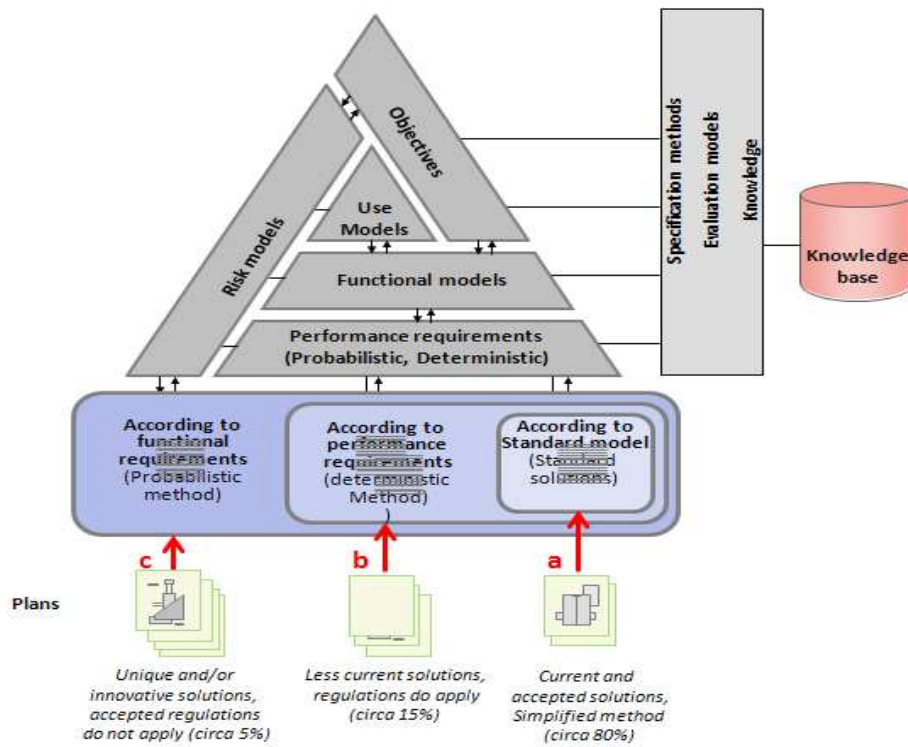

Figure 3. Vision on a durable anchoring of development of building regulations
(Source: Scholten *et al*, 2010)

Table 1. Explanation of captions used in figure 3
(Source: Scholten et al., 2010)

<p><i>Objectives.</i> Regulations must follow from a single coherent system of societal objectives. It is best to record these in a separate part of the regulatory system.</p> <p><i>Risks models.</i> Absolute guaranties for safety, health and sustainability cannot be given. Objectives always deal with <i>possibilities</i> and <i>risks</i>. They deal with the possibility of collapse, the risk of permanent physical injury or death, and the possibility of environmental damage. The present regulations often provide strict limit values for these possibilities and risks. Does exceeding these limit values immediately lead to unsafe and unhealthy situations or limited sustainability? Depending on varying circumstances or the use expected, a building may still, in an acceptable measure, meet the objectives laid down.</p> <p>That is why we will again have to standardize the whole system of regulations, standards and limit values according to the objectives by means of risks models and theory of probability. These models must become an integral part of the regulatory system. This too would greatly simplify regulation.</p> <p><i>User models.</i> We can only translate objectives into specifications for buildings if we also know how these are going to be used and who their end users will be. Models are necessary because of the variation of use in practice. That is why there is a need for realistic rules and regulations <i>user models</i>. By projecting these user models onto the model of a building, in terms of floors, working spaces and partitioning elements, we can then list functional and performance requirements.</p> <p><i>Functional and performance requirements.</i> Functional requirements describe the requirements of a building in a functional sense. The performance requirements we set for a building and its parts depend on their function and use.</p> <p><i>Modifiability.</i> Naturally, the rules and regulations system reacts to ever changing societal opinions. In the past decade, for instance terrorism, climate change and sustainability took top positions in agendas. Undoubtedly, new requirements and objectives will be added in the coming decades which cannot be foreseen for the moment. One should be able to change the rules and regulations as easily as possible, with minimum economic effects for users and real estate managers, while retaining previously acquired rights.</p> <p><i>Knowledge.</i> Many rules are clear-cut. But it is not always clear why certain rules exist or why others <i>don't</i>, or why specific terms are used. Often, the persons involved have stored this background knowledge in their minds, but it is not at all or hardly available to third parties. That is why this knowledge has to be publicly recorded so everybody will be able to properly interpret and apply them.</p>
--

Methodical aspects also deserve attention. One can formulate regulations in such a way that computers can interpret them. This can then be linked up with the latest generation of computer assisted methods and systems already used by the industry. Methodology renewal is also essential to keep the increasingly complex law-making system manageable.

The government wishes to withdraw from markets that might just as well be left to trade and industry, as underlined in the report of the Dekker Committee 'Privaat wat kan, publiek wat moet' (private whenever possible, public whenever required).

Differing from most of the other industrial sectors, the knowledge process in the building sector is highly dispersed, as has been shown earlier and depicted in figure 2. Most of the parties only take responsibility for their own part in the process; nobody feels any overall responsibility.

The system of regulations and Standards forms an essential link in the knowledge process, so we should continue to invest in it for further development and maintenance. However, that does not happen sufficiently.

In figure 4 we have indicated several points of improvement in the knowledge cycle. The question now arises: should the government leave all this to the market?

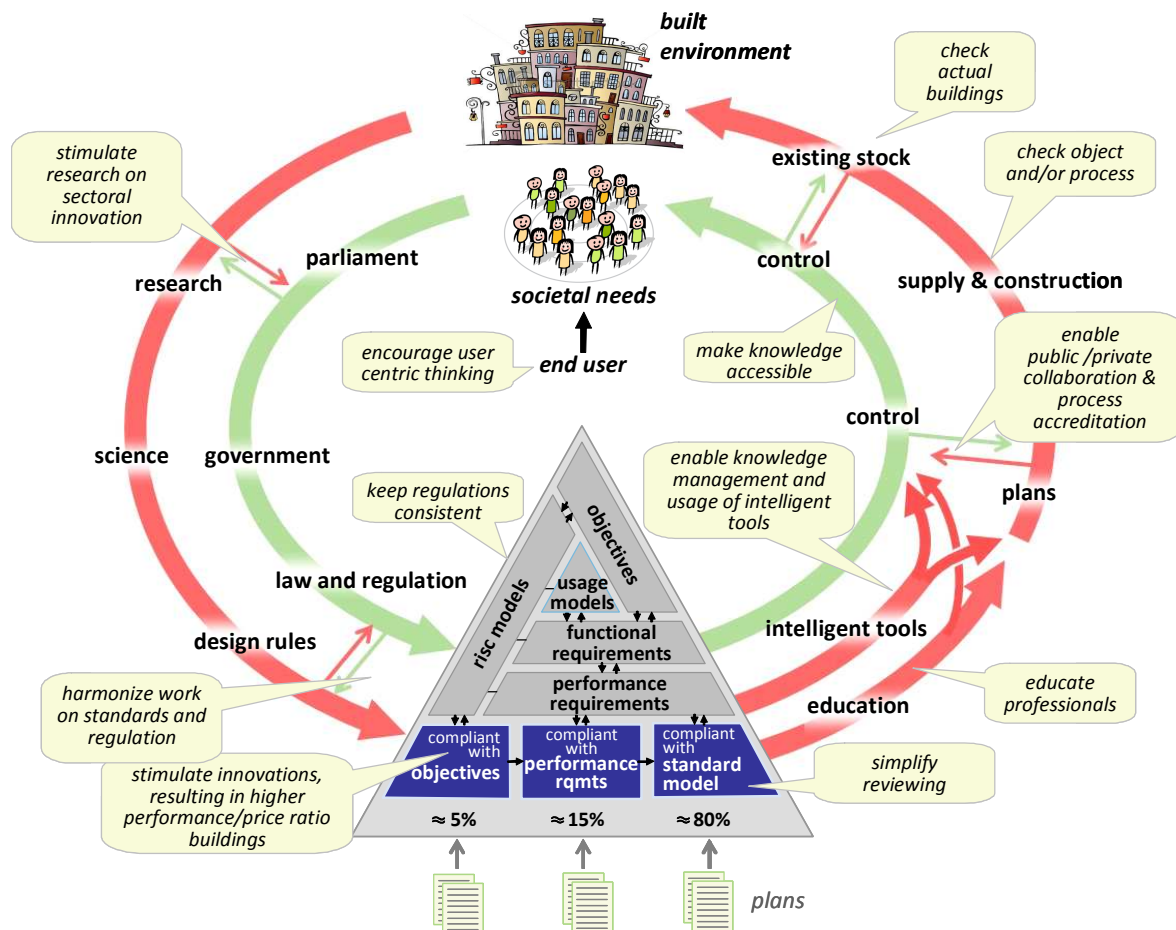

Figure 4. Vision on future development of building regulations in closed and linked public and private law chains of knowledge
(Source: Scholten *et al*, 2010)

Another option is: a combined public/private system.

The present public system of assessment against building regulations is directed at the granting of an Omgevingsvergunning (environmental permit). Moreover, the insurance industry could develop a generally acknowledged private assessment system, covering everything, including conveyance. In this scenario insurers should only be willing to insure risks after a commissioning client has first performed such an assessment. This reduces risks for the insurer and increases guarantees on quality delivered for consumers. For simple construction works, built according to the solutions method, such a guarantee is not required; in which case the client can choose for building with or without a guarantee. The private system proposed is also suitable for matters concerning labour conditions. Should contractors construct buildings with such a guarantee, the authorities could then reduce their administrative charges, or they could even decide to drop the public law assessment altogether. In any case, this solution would require less public law

inspection on the spot. In the same way an insured guaranty at the sale of a building can prevent claims of insufficient performance.

In an organisational sense, acknowledgement should be organised for independent technical-legal arbitration, so that for applicants which have a conflict with authorities on technical points, the dispute can quickly be settled on technical-legal arguments. The formal road of objection and appeal according to the Algemene Wet Bestuursrecht (General Administrative Law) is much too cumbersome for this.

Furthermore, the knowledge should become easily accessible and actively promoted through training, publication, the internet and knowledge systems – and transferred to - professionals in - the building chain as well as the law enforcement organisations.

Moreover, emphasis could shift from design to process assessment, and possibly to process certification. That is to cover the complete process from design to the building process, including quality management and guarantee after conveyance. This quality related thinking (ISO 9001) has been accepted in many sections of industry, but what would this mean for the organisationally strongly fragmented building sector? The ultimate test in quality related thinking is customer satisfaction, but as already stated, the actual customer, the end user, generally, takes not part in the Dutch building process. Besides, designers, contractors, suppliers, and authorities have shared responsibilities: nobody feels accountable for the whole process. Although integrated contracts are becoming increasingly popular -owing to the need of integral accountability -they still only constitute a tiny part in the present market.

Furthermore, we now see the development of computer-interpretable provisions and regulations and knowledge based rules as well as methods of numerical analysis; thus everybody can automatically assess a design according to BIM, building information models, before applying for a permit (Gielingh *et al.*, 2010). Naturally, the applicant and law enforcing organisation ultimately remain accountable for the integrated design. Only when builders and applicants do have the overall knowledge, buildings will be realised that not only actually meet the regulations on paper but also in practice.

Moreover, with a coherent approach also methodical improvements can be implemented and monitored leading to consistency that, by means of reference, forms part of the same chain of knowledge.

5 Economic and societal relevance

Structural regulation fulfils a key role in the translation of essential societal needs regarding the built environment. As we are all regular users of that built environment, whether it be living, working, recreating or travelling, that regulation is of essential societal significance.

However, everything has its price. When we look specifically at the development, learning, applying, enforcing and implementation of the rules and regulations – which we have symbolically represented with the two knowledge circles in figures 2 and 4 – then this refers to a process which involves thousands of specialists on a daily basis. There are no exact figures on the commitment of people and costs.

Also, the construction, management and maintenance of real estate involve substantial amounts of money. Some expenses directly contribute to the quality of the built environment; other expenses are needed solely to apply regulations, so at the best they contribute indirectly to the safety, health and sustainability of buildings. The latter expenses are probably partly unnecessary and too high.

Moreover, costs arise when a design or existing works does not meet the regulations set, because the applicant simply knows them insufficiently and/or due to limitations in the enforcement system. At present, enforcement takes place mainly by means of random checks based on paper building plans. Enforcement should take place much more on the basis of buildings actually constructed, specifically with a view to the real risks for which these regulations have been written.

According to some estimates tens of millions of euro could be saved with our proposals for renewal of the system as a whole. When the knowledge circle is ignored there is a risk of needless costs for society. The unnecessary costs to renew the existing building stock in case of Building Decree 2012, developed with the only goals to diminish the volume of regulations to get less administrative burden, are estimated at €5 mld and the administrative burden will still be the same. On the other hand a lot of interpretative discussions are expected and technical insufficiencies are not solved. The reason for more than 170 questions of the Parliament to the Government.

How much the improvements we propose will actually yield, cannot be estimated accurately, but with a conservative estimate we set it at 10-20% of the direct costs; with an estimated annual regulatory effort of € 1.2 – 1.6 billion and a building production of about € 60 billion, this would lead to an annual cost reduction of € 120-240 million for local authorities and trade and industry (Scholten *et al.*, 2010). We have here excluded the societal and economic advantages for the building sector, management and use of real estate, but these advantages will as estimated also be very high, expressed in money: hundreds of millions of Euros per year.

Energy saving goals require reform of building regulations and control

Henk Visscher, Frits Meijer

Abstract:

The energy saving potential of the building stock is large and considered to be the most cost efficient sector to contribute to the CO₂ reduction ambitions. As long as the price of renewable energy is still not competitive with fossil energy, the energy saving goals can only be reached supported by severe governmental policies. In Europe the Energy Performance of Buildings Directive is a driving force for member states to develop and strengthen energy performance regulations for new buildings and energy certificates for the building stock. The goals are to build net zero energy buildings in 2020 and to reach a neutral energy situation in the whole stock by 2050. Research delivers signals that, although technically feasible, actual results of the policies and regulations are not as expected. Theoretical energy use calculated on base of the design standard for newly built houses and assessment standards for energy certificates of existing dwellings differ largely from the measured actual energy use. The potential of the existing building stock is even higher, but harder to harvest. The paper will present findings of several research projects providing evidence of malfunctioning of current approaches. Based on this, the paper will present some ideas of innovations in the regulatory and control systems and suggestions for research to support alternative solutions.

Keywords:

energy saving, energy performance, building regulations, building control

1 Introduction

The European building sector is responsible for about 40% of the total primary energy consumption. To reduce this share, the European Commission (EC) has introduced the Energy Performance of Buildings Directive, the EPBD (2010/31/EC). This framework requires member states to develop energy performance requirements for new buildings and a system of energy performance certificates for all buildings. It also requires member states to develop policies that require to built only 'low energy or Passive Houses' by 2020. More and more countries, but also regions or municipalities, formulate ambitions for net zero energy or carbon neutral houses also on the shorter term.

Most savings can be realised in the existing stock. National and local governments have formulated ambitions, stimulation and subsidy programmes to stimulate large scale renovations.

Formulating ambitions and sharpening regulations is relatively easy to do. Technical solutions are currently available to realize the passive house standard in building projects. There is quite some evidence however that the mainstream of building processes do not lead to the pre-defined quality. Traditionally the municipal departments of building control in most countries had an important role in assuring that building plans and construction processes would lead to buildings that meet the minimum required quality levels. There is a tendency to put more emphasis on the responsibilities of owners and private parties to ensure quality. This means that the private parties will have to improve their working process and will have to learn to handle performance guarantees. Owners will require guarantees from the designers and building companies for the quality of their property. Certification and accreditation of parties, processes and products will become more important for building processes in general.

For the realization of high energy performance standards, a reliable quality assurance system will be very important. In most countries that have some experiences with passive houses some form of performance guarantee and associated quality assurance scheme exists. It is important to study these examples.

In this paper some developments in building regulations and building practice will be described to highlight the role of building regulation and building control in the context of the increasing energy saving target for new as well as for existing dwellings. We start in section 2 with an elaboration on the trends in regulations and building control. In section 3 the results of a study on the relation between the levels of energy performance regulations and the actual energy use in newly built houses are presented. In section 4 we show the example of certification of passive houses as a valuable contribution. In section 5 the situation of the development of policies for the existing dwellings is described. Section 6 presents some conclusions. Finally section 7 introduces the goals and working programme of the CIB-TG79 task group 'Building Regulations and Control in the face of Climate Change', which addresses all these issues.

2 Developments in systems of building regulations and building control

Building regulations are the subject of an ongoing debate between, on the one hand, those in favour of deregulation and reducing the administrative burden and, on the other hand, new quality demands that require government intervention. Energy and climate change concerns belong to the core of policy developments of the European Union and lead to directives that demand member states to develop regulations and enforcements schemes that ensure very energy efficient new buildings and instruments that stimulate the improvement of the existing stock. So, although the general development in European countries leads to less government intervention in the building sector, in the field of energy efficiency the number of regulations increases and become more stringent.

Currently in the Netherlands, both sides of this debate appear to be gaining in importance. The desire for deregulation is leading to the opinion that greater emphasis should be placed on the responsibility of property owners, which could lead to less government intervention. However, the existing forms of quality control for private actors in the Dutch building industry seem to be

of quite a low standard. Accidents occur and physical quality does not appear to be sufficiently important. As the CO₂ and energy targets increase, stronger regulations and accurate building control become a priority. In the past ten years, it has become increasingly clear that the quantity and quality of assessments carried out by many municipal authorities leave something to be desired (VROM Inspectorate, 2007).

In this context we should remember that the client and the parties who engage for the design and construction stages have primary responsibility for complying with regulations. When a building permit is granted, this suggests that the plan has been shown to comply with all the regulations. But this is not the case. In practice, a permit is granted because, during the checking process, the plan was not found to deviate from the regulations.

We will now return to the continuing call by politicians for greater deregulation and easing of the administrative burden. In 1997 we contributed to the building-regulations project as part of the MDW (Market Forces, Deregulation & Legislative Quality) programme of the Ministry of Economic Affairs. The purpose of our research was to formulate deregulation proposals on the basis of examples from other European countries (Visscher, 1997). Notably, in those countries, many private-sector parties are involved in assessment and inspection. We have studied (Visscher, 2000) how the responsibility for these tasks could be transferred to the private sector in the Netherlands too, primarily through the certification instrument. The Ministry of Housing, Spatial Planning and the Environment (VROM) also took up this idea. Since the end of the 1990s, it has been developing a process certificate for assessing building plans against the requirements of the Building Decree.

In current government is aiming to drastically reduce the administrative burden. Again, the field of building regulation is seen to have a great deal of potential in this regard. A few years ago, the government appointed the Construction Sector Fundamental Review Committee (Commissie Fundamentele Verkenning Bouw) chaired by Sybilla Dekker, a former Minister, to draw up proposals for the far-reaching simplification of building regulations. The committee recommended the abolition of preventive assessment of building plans by local authorities. The client should be responsible for complying with the regulations and should also ensure that sufficient checks are in place. It can engage a certified body to do this, but there may be alternatives. The role of the municipal authorities will shift towards that of process auditing, i.e. supervising the checks. The question is then: how this can be put into practice?

In many countries there are problems with a lack of compliance with building regulations, and this often serves as a stimulus for reviewing and improving the system of building control. The considerable pressure to deregulate in the Netherlands has parallels in other countries. There is a clear trend towards increasing the role of private parties. In many countries, the role of local authorities in carrying out assessments and implementation inspections has virtually disappeared.

Therefore it is interesting to study innovative ways in which quality is guaranteed by private parties. The certification of passive houses is a field that requires building actors to transform the usual building process into a performance based approach and to learn by doing. In section 4 we illustrate quality assurance processes for passive houses that exist in some countries. First in the next section the need for more quality assurance will be illustrated.

3 The realisation of required energy performances in building processes

In 1995 energy performance regulations were introduced in the national building regulations. It consists of a calculation method laid down in a national standard EPN (energy performance norm) and a limit value, the EPC (energy performance co-efficient). Since the introduction the EPC was sharpened several times. It started at 1.5 in 1995 and since the 1st of January 2011 it is now on the level of 0.6. The EPC is a non dimensional digit. All building characteristics and building services that affect the energy demand for space and hot water heating, ventilation and lighting are incorporated in the calculation of the energy index (EI), which is the basis for the EPC.

After more than 15 years of Energy performance regulations in the Netherlands, only few representative statistical studies were conducted to assess the effect of the regulation on the actual energy use. The samples were of limited size. In two of these samples, no statistical correlation was found between the EPC-level and actual energy use per dwelling or per square meter. In the analysis of the WoON survey, carried out on behalf of the Ministry for Housing, Planning and the Environment in 2006 and which is representative for the Dutch housing stock, no correlation was found between the different levels of the EI and the actual energy use per dwelling and per square meter.

We found that building characteristics (including heating and ventilation equipment) were responsible for 19 to 23% of the variation in energy used in the recent building stock. Household characteristics and occupant behaviour seem to be responsible for 3 to 15% of the total variance. Neither our study nor the studies found in the literature allow to state that building characteristics, household characteristics and occupant behaviour altogether are responsible for more than 38% of the variation on energy consumption of dwellings built after 1995. Therefore at least 62% of the variation in energy use is unexplained yet.

There are indications from literature that the explanation for this remaining part could be related to buildings being realized differently than written in official documents and to HVAC services running under very different conditions than assumed on paper. A report by Nieman (2007) showed that in a sample of 154 dwellings, 25% did not meet the EPC requirements: the EPC was incorrectly calculated; nevertheless the building permit was issued. In 50% of the dwellings, the realization was not in accordance with the data used to calculate the EPC. Gommans (2007) monitored for 17 years the energy performances of energy efficient buildings. 40% of solar boilers appeared to function poorly. Only 25% of the heat pumps reached the expected efficiency. This was essentially due to realization faults, lack of control and lack of continuous monitoring. Another study by Elkhuisen e.a. (2006) in office buildings showed that up to 28% energy could be saved by better monitoring.

Taking into account the fact that tightening the EPC did not lead to less energy use for heating and that 62% of the variation in energy use is still unexplained, it seems legitimate to be careful about a further tightening of the EPC and to search if there are more efficient means to really decrease the energy consumption of newly built dwellings. This could be done by ensuring a correct realization and monitoring of the calculated performances, putting attention on the knowledge needed by contractors and on an effective building control process.

4 Certification of passive houses

According to the EPBD recast before 2020 all newly built buildings will be at the level of nearly zero energy buildings. In section 3 we have seen that in the Dutch practice current required levels of energy use are not met and it is not likely that the European targets will be realised by only putting the regulations at a higher level. In this respect it is useful to look to examples of quality assurance of passive houses that exist in some countries.

Quality assurance of passive houses, and associated technologies, has its origin in the verification and prediction of a restricted energy demand. Passive house project certification is not focused on issues like stability, safety, or more general environmental performance. Guaranteeing an energy performance is a relative new issue in building processes, requiring a shift in general thinking from means contracting to performance contracting. The urgency of the energy issue requires a swift implementation of (energy) performance contracting in the construction sector. In this paper passive house certification is regarded as an innovation in building processes to provide better building quality in general. Related to the introduction of passive house certification schemes the issue was raised how such initiatives can also upgrade knowledge in the construction sector.

Different European countries show a different embedding phase and related market penetration of passive houses and quality assurance of passive houses. Some countries like the UK, Ireland and the Netherlands are still starting up initiatives, while others like Germany, Austria, Switzerland, Belgium, France, and so on, provide a framework for grants and/or tax reductions and associated quality control procedures. In Western Europe the passive house standard is still a voluntary standard, while regions in Central Europe are already developing initiatives to include the passive house standard as a legal instrument and/or obligation for new constructions. Existing voluntary certification initiatives are different in different countries. Some harmonization between the different national initiatives might be interesting. Especially countries with no certification can already duplicate the most successful initiatives. Early adaptor countries have developed financial aid for passive houses, as well as a performance oriented quality approach for the design and construction process of passive houses. Control of quality of the design process, the construction process and the post construction inspection and testing of passive houses is considered as an essential feature, before stimulating the dissemination of information considering best practice demonstration projects.

Since the implementation of the European Directive 2002/91/EC and since the introduction of project related energy performance requirements and e.g. the passive house concept, problems about guaranteeing (energy) performances and information flow among building partners and quality control have become more significant. The EPBD and the passive house certification are being used to improve product and process modelling in commissioning for existing and new buildings as they are accompanied by a process of certification. EPBD calculation procedures are in many countries still not adapted to specific passive house technologies. This means that in many countries for passive house projects both PHPP and EPBD calculations have to be performed. The cost of an extra certification next to the legal energy performance certificate is considered to be a bottleneck.

As part of the process of demonstrating compliance with required energy performance, assessment of the energy performance of design of new dwellings is becoming mandatory in many countries and regions. For most buildings with a building permit, requirements are set for the energy performance as a consequence of the implementation of the EPBD, but also aspects of indoor climate and ecological criteria are sometimes introduced at the same time. It is generally perceived that a good energy requirement does not necessarily bring thermal comfort and good indoor air. Especially summer comfort can be a critical issue to be included in passive house certification as well as the proper working of balanced ventilation systems. In many cases the existing structures for energy performance evaluation, developed in the framework of the EPBD, are not sufficient to guarantee the quality and definition of the passive house.

PHPP software is mostly used as a basis for certification of passive houses. Its main advantage compared to other design and evaluation tools is that it has been specifically created as a design and certification tool for passive houses and that it regularly takes up new research results in its calculation procedures. Certification of passive houses usually also includes an air tightness test. In some cases, also the functioning of technical systems and its effect on indoor climate is directly, or indirectly through evaluation by PHPP, considered. Some countries express the need to include, besides the PHPP calculations, comfort criteria (e.g. Belgium) or health criteria (e.g. UK, Austria). A differentiation in standard including low energy definitions, like in the Klimahaus CasaClima programme, can contribute to success of widespread certification.

In most advanced countries educational programmes for specific target groups were introduced, accompanying the introduction of certification systems. Experiences in Germany, Austria, Switzerland, Belgium and Italy illustrate that quality assurance of passive houses is necessarily related to the provision of passive house education initiatives. New fields like non-residential buildings and renovations require for the further development of more specific quality assurance procedures. It is not clear if the strict passive house definition can or should be maintained, especially since it is sometimes difficult to achieve for small houses or renovations. Also, PHPP calculation procedures in themselves are often not sufficient to evaluate the design of, for example, technical systems in office and school buildings.

5 Policies and instruments for energy reduction in existing dwellings

The largest energy saving potential is in the existing building stock. National and local governments have formulated ambitions, programmes policies and instruments to stimulate the improvement of the energy performance of the existing stock. The most important policy tool required by the EPBD in the European member states, is the issuing of Energy Performance Certificates. In most countries it is current practice to produce an energy label for a building at the moment it is sold or re-rented. In the Netherlands the labels are also mandatory for all dwellings of social housing associations. The label indicates the energy demand for heating and cooling. It is a communicative instrument and there are no obligations to improve buildings as a consequence of a low label, but the labels are used as a basis for recommendations of improvement. Subsidy schemes are more and more related or combined with the labels. And there are some signs that a better label affects the price of houses.

The label data bases already cover a reasonable share of the housing stock in the Netherlands. They form a basis to monitor the progress of the renovation practices. Besides this it is also

useful to study the effect of improving energy labels on the reduction of the actual energy use. Later in 2011 accurate figures and insight can be produced by the OTB Research Institute of the Build Environment of Delft University of Technology. As for now already some expectations can be formulated.

The progress of renovations and energy upgrading measures stays far behind expectations and formulated ambitions in 2008 when most of the policies, covenants and improvement programmes were set up. The social sector in the Netherlands is still relatively large (35%), well organised and relatively rigid. A few years ago the sector formulated ambitious programmes, but these are nowadays scaled down because of several reasons. The economic crises reduced the financial position of the housing associations. The housing market also dramatically slowed down which also affected the funding for renovations because this largely depends on the sales of property. Also it proved to be difficult to get improvement of tenant for renovations that require an increase of the rents (70% of the tenants have to agree). It is hard to assure the saving of energy costs resulting of the improvement of the dwellings. The actual energy use is largely influenced by the use and behaviour of the tenants. The aforementioned study of OTB will provide good insight in this relation, but there are already some preliminary figures that demonstrate the difficulty in ‘forcing’ reduced energy use by improvements of dwellings. The dwellings with the worst energy label (G) in practise use far less energy as expected, while the most advanced dwellings (A) use much more. This can be explained by a combination of the rebound effect and an increase in comfort level of the dwellings.

In the home owner sector the issuing of energy labels stays yet far behind. Although they were mandatory, until now there has not been an enforcement system. From 2012 on a label will be required for each property transaction and this will be checked by the notary in the Netherlands. Energy labels will become common practice and affect the sales price. Still there are no obligations foreseen to make improvements and higher labels mandatory. It is hard to require investments and property rights are probably an obstruction. Still there are some ideas for taxation measures. Bad labels could be punished with higher transaction taxes or higher property taxes than good labels. Such measures were suggested by the Platform for Energy Transition in the Build Environment. It is not likely that these measures will be adopted by the government on a short term however. But if the saving potential of the existing stock is taken seriously it seems that firm policies and regulations will be needed.

6 Conclusions

The necessity to drastically reduce fossil fuels seems without any doubts these days. The built environment offers a large potential of savings. Severe insulation and product innovations can reduce the energy demand for heating and cooling for a large part. The remaining energy demand can be delivered by renewables like sunlight and heat, district heating, heat pumps etc. The remaining electricity demand for appliance’s can in the first place be reduced by further product innovation and then be provided by photo voltaic panels. Solutions are there. There are no reasons not to apply this in new buildings at a large scale on the short term. However, a successful transition requires a lot from the designers, engineers, installers and builders. They will have to use new techniques and improve the quality and accuracy of the work. Solutions have to be found that are robust. Solutions that are vulnerable for the application in practice

and/or for the unpredictable use of the occupants should be avoided. Evaluations of the current practice show that there is still a large world to win. The building regulations should set demanding targets, but what is surely needed is a better quality control in the whole process. This control should be carried out by the building practitioners themselves. They are the experts! But this will only start working if it is demanded and supported by regulations for certification of people and processes.

Although the potential is higher, the existing stock will be harder to tackle. Experiences show that it is hard to increase the numbers of severe renovations. And even more that the savings in renovated dwellings stay behind expectations because of rebound effects. There are many barriers: renovations are expensive, occupants mostly do not want the trouble and sometimes aesthetics make a change of the facade unwanted or impossible. On the other hand a large share of the current existing stock will have a very long life span, just because the replacement grade by new dwellings will simply be too low to provide enough new dwellings. In this perspective, there will always be a large need for renovations to expand the life span and this provides possibilities to improve the energetic quality. The fear however is that this 'normal' process goes too slowly. Maybe there is still a need for further smart product innovations to develop solutions that have a high contribution to the reduction of energy demand, are cheap, easy to apply and do not cause trouble to the occupants. The fast decrease of the price of PV cells is promising. The markets need to be stimulated by regulations. It is especially hard to persuade homeowners to invest in energy saving measures. Besides that more insight has to be developed in the effect of behaviour on the actual energy use. Possibly the pricing of energy could contribute to more consciousness use.

7 CIB Taskgroup 79

Since a few years the attention for building regulatory systems and enforcement procedures is growing. Various developments in society, politics and the construction industry have influenced changes in the systems of building control in the last 20 years. The influence of climate change and the related demands on buildings will have a very strong impact of further transformations in this field. Therefore CIB has established Task group 79, Building Regulations and Control in the Face Climate Change. It will be useful to compare developments of the systems of building control in countries worldwide. How do the various countries deal with the demand of deregulation and privatization of enforcement tasks? What are the effectiveness and efficiency of the systems? Could green promotion incentives be incorporated to improve the systems? How do the public regulations and enforcement systems contribute to the basic quality of buildings? Are the current systems suitable to ensure that buildings will have a very low energy demand and are comfortable, healthy and safe at the same time? What are the ideas to improve or change the systems? And what will be the impact on these systems from climate adaptation measures in the longer run?

The task group will make an original contribution to the CIB Sustainable Construction priority theme. The majority of research on sustainable construction addresses the development of innovative techniques. However, there is now awareness that it is equally important that mechanisms are developed which can effectively implement the new techniques on a large scale. These will include building regulations which incorporate appropriate incentives for the

promotion of the green agenda and which therefore stimulate the use of new techniques. Equally, systems of building control will also be required which are capable of monitoring the effective and accurate design and construction of the buildings. These and similar issues will be addressed by the proposed task group.

7.1 Working programme

The core interest of TG79 is: new alternative visions on the role, the system, the formulation, the content, the organization of building regulations and building control because of the changing circumstances of climate change.

The changing circumstance leads to research to address:

The balance between command and control regulations versus incentives;

The balance between the role of public and private parties in carrying out the tasks of control;

The new role of control and supervision: form a strong focus on control of the design to more monitoring of the building process and testing of the quality of the final building and post occupancy monitoring.

The role of regulations for existing buildings and adaptive re-use of buildings.

Alternative approaches to reduce the gap between level of energy regulations and level of actual energy use?

Contributions of members of the task group can be various and will report about recent research findings from different countries worldwide that lead to new insight in these matters.

Urban Villages in China

Abstract:

There are two main types of land ownership in China – state owned land, and land owned by village communes. During the rapid urbanization of China in the past 30 years, state owned lands were sold and developed into high densities apartments. These apartments were built literally surrounding existing rural villages. Village lands were, however, not allowed to be developed because of its rural history. But when the villagers saw the profits of development, they simply build new apartments illegally at rates and densities even higher than those on state owned lands. By now, the political problems of these illegal developments are too large to be handled by local city governments. Hence, as we now see, there are high density apartments built by villagers right inside city centres. Very often these apartments are poorer in qualities. This paper traces the history of this development, and tries to induce property right implications on excessive land exploitation, in the absence of effective building regulation and control.

Keywords:

building regulation and control, property rights, state owned land, urban villages, village communes.

1 Historical background

In mainland China, there was basically a feudal land system before the Chinese Revolution in 1911. After 1911, a system of private land ownership was still, by and large, enforced by the Chinese Nationalist Party. The Communist Land Reform started in 1946. Basically in this reform, land and other properties of landlords were expropriated and redistributed. And after the Peoples' Communes and the Great Leap Forward in the 1950s, collective agricultural land ownership was established. Starting in 1978, these collective lands were assigned to individual families under Household Responsibility Contracts.

By now, there are basically three types of land ownership in China: (a) land for family village-houses (宅基地); (b) Collectives' land (集体所有土地); and (c) state owned land (国有土地). Except for a small portion of land on which family village-houses were built, lands in China were basically non-privately owned.

In December 1987, land use rights were first auctioned in Shenzhen. State-ownership rights on land were then separated from use rights; thus allowing private ownership of land use rights for a given number of years, to be bought and sold.

After 1989, the rights to develop land were decentralized - down to the local “xian” level governments. Xians in China should not be confused with counties in the west. Xians are much smaller: there are altogether 2,860 xians in China. Each is, on average, 3,000 square kilometers in area; and 0.45 million in population.

The tax sharing reform in 1994 allowed the Chinese central government a much larger share of the total national tax revenues than that of xians. But on land sales revenues, the xians share much more. In order to make up the loss, local governments started selling much more land.

The actual shares are as follow. Xians can sell land development rights to prospective developers and industrialists; and share 75% of the land sales proceeds; and the remaining 25% goes to Beijing and higher level governments. On the other hand, xians share 25% of the valued-added taxes, which are levied at 17% on any production on the land sold upon development. Xians rely on these incomes to build infra-structures and other facilities to attract even more investors. See Cheung (2009). Under this xian system, land sales income, plus subsequent value-added taxes, are the keys to government finance; and hence there is a financial dependence on land sales.

Cheung (2009) argued that the introduction of the xian economic system was the most influential economic institution contributing to China’s economic success over the past twenty years. It took just 30 years for the urbanization rate to grow, from less than 20% in the early eighties, to 46% in 2009. Urban population in China is now 0.622 billion. See United Nations Statistics (2007). Together with the corresponding growth in income, house prices had increased tremendously, while cities had sprawled into rural areas.

Given this background of rapid urbanisation, the demand for housing in the cities is so large that villagers are more than willing to give up farming entirely, and start thinking of development on their farmlands. Local xian governments were able to acquire many of these farmlands and legally covert them into state-owned land on which land use rights were sold for the purpose of development. Seeing the huge profits themselves, many villagers simply refuse acquisition offers, and start planning high rises for themselves.

2 Urban villages

Urban village is a special phenomenon in the mainland of China. In the amended version of Constitution in 1988 (The National People’s Congress, 1988), a clear statement was made saying that, “Land use can be transferred according to the law”, but apparently rural collective lands were excluded as exceptional. Originated from the rural collective land system, urban villages can then be distinguished from other non-village urban regions for their incomplete nature of property rights. Compare to state-owned urban lands, the incomplete property rights in urban villages are also called the “small” property rights, for buildings on rural lands together with the land parcels themselves are not allowed to be transferred.

Previous studies on urban villages are mostly in Chinese. There are two categories, one is focusing on the urban villages as a small society and tries to discuss it using a sociological perspective, the other is focusing on economic analysis, especially on benefits/costs analysis. The former includes the new society issue by Lan (2003), and the self-help housing issue for temporary migrants by Chan, Yao, and Zhao (2003). The latter includes the institutional change analysis by Li and Meng (2004), the public interest analysis by Wang and Ren (2009), the urban village renewal analysis by Liang and Cai (2009), the property rights analysis by Jiang and Wang (2002), and a general economic analysis by Zhou (2007). The only paper with a topic close this study is by Gu and Zou (2002). In their study, they calculated the total rent receivable for urban villages in Guangzhou and their nearby non-villages estate. The comparison shows that urban villages are less efficient for the reason of rent dissipation. However, a fatal defect of their study is that the comparison was between total rents, instead of per floor rents. Since urban villages are much lower in terms of height, such comparison is simply imprecise. Nevertheless, even using their data, the comparison of per floor rents still supports the argument.

3 High densities in urban villages

The urban village case provides a rare example demonstrating both a production change and a possible contract change induced by incomplete rights. The land use pattern in urban villages is completely different from nearby non-village estates in terms of the higher densities, measured by the site coverage (SC), and the lower rents. The higher densities indicate a possible overdevelopment problem and the lower rents indicate possible rent dissipations. Table.1 shows the site coverage values and the estimated per square foot rent per month for six urban villages in Shenzhen in comparison with nearby non-village residential estates (TR--Total Rent).

Non-village estates are normally under site coverage controls, for example, ≤ 0.25 for multiple floor residential buildings in Shenzhen (Shenzhen Land and Planning Council, 1997, 2004, and 2007). It is normally believed that such regulations, if set right, can confer property rights and reduce transaction costs. However, if set inappropriately, certain rent losses can be induced. In Shenzhen's case, planning regulations are set as unified metrics, regardless of location difference, which implies that a possible underrate problem, especially for locations in urban centres. However, the total rent collectable psf of land for most urban villages is still lower than non-village estates, showing that, except for a few central locations, more severe rental losses can be expected for urban villages. The planning regulations are thus playing a controversial role similar to a double-edged sword. Once, as a first element, rights are delineated, voluntary exchange can resolve externalities, if and only if there is no or minimum transaction cost. Furthermore, rules and laws specifying detailed metrics based on theoretical deduction or empirical analyses or both can be set as secondary tools to reduce disputes and smooth transactions. Hence, planning regulations can be so classed as facilitators, but only if such metrics--site coverage or plot ratio--can be set properly across each location. Without the initial rights setup, it seems no way to specify any detailed rules and accordingly, marked case 1, there must be unavoidable excessive land exploitation and value losses, as we have seen in urban villages. However, if the metrics are set inappropriately for all or some locations even with well set initial rights, they may still put unnecessary restrictions on profitable development and thus value losses, which can be even worse than case 1, as we have observed in a few central locations, marked case 2. If the metrics can be set properly for each location with initial rights

well set (case 3), then as we have observed, non-village estates can bring more rental income not only in terms of total collectable rent, but also in terms of rent per floor unit of land, thereby surely more superb than the other two cases.

Similar patterns can also be found in Guangzhou and Xi'an, which represent the other two main cities with large amount of urban villages. Table. 2 shows the situation for five urban villages in Guangzhou and Table. 3 shows the situation for Xi'an.

The density pattern can be clearly identified using satellite images (free online). Map.1 is an example showing the difference between Gangsha in Shenzhen and its nearby non-village estates.

4 The cost of assembly

Land owned by village collectives can be viewed as a common property which, in theory, is subject to common exploitation and therefore rent dissipation. See Gordon (1954) and Cheung (1974). It is, however, not conclusive that the profits per square foot of the site area in urban villages are higher or lower. That will depend on a number of other factors including: the height of the buildings constructed, and the cost of construction. In Tables 1, 2, and 3, comparable examples of similar building heights and qualities are chosen to simplify the analysis.

Comparing to nearby housing developments, it is, however, clearly observed that (a) the densities of urban villages (SC) are much higher; and (b) the rent collected per square foot built floor area are much lower. However, comparing the two columns labelled as Total Rent (TR psf) in each Table, there is rental dissipation but not distinctive. The differentials in rent depends more on the densities allowable by law.

An alternative view is to include the cost of assembly as a substantial entrance fee to develop the land legally. A typical village may consist of hundreds of families. Getting them all to agree to a scheme of acquisition offered by the local government is an enormous task. More often, the price offered to acquire a piece of farmland is often far too low compared to the potential profits to development the site.

According to the Alchian-Allen Theorem (see Umbeck 1980), imposing a substantial entrance fee to the consumption of a good would result in either the consumer (a) not paying the entrance fee at all; or (b) paying the entrance fee but consumes a much better quality product. In cases of the urban villages, apparently the costs of assembly are too high compared to the foreseeable profits of selling the site to the local government or to developers. Given a high cost of assembly, it would also be very costly for one villager to negotiate with all his neighbouring villagers to agree that everybody would build less, thus enabling a better environment. An agreement of this kind is hardly enforceable. Hence, despite of the risk for being prosecuted, villagers may build up to the highest possible density, leaving minimum common spaces in between, and thus resulting in much lower rentals. This situation could be dealt with using game theories, but for the time being, the high cost of enforcing a low density agreement is sufficient for our purpose.

A testable implication of this view, of assembly cost, is that individual blocks within the urban village development were owned and sub-divided by village families even before construction.

The urban village constructed as a whole can be viewed merely as a means to enjoy economies of scale by hiring one a single contractor. Such subdivisions are largely consistent with the facts of ownership, although the legality of such ownership is questionable.

6 Conclusions

In this paper, we had introduced the background for urban villages in China. We also observed that these villages are often built in higher densities, but rented out for much lesser incomes. Further studies are needed to determine the level of rent dissipation under common ownerships. We also find that assembly cost and the risk of being prosecuted are key factors in determining whether villagers would develop the land illegally for rental incomes. Detailed data on rental and project data are necessary for the verifications of alternate hypotheses explaining the high development densities in urban villages.

Abstract:

This paper presents an analysis of the main initiatives implemented in Portugal aimed at improving the environmental performance of buildings. The study is focused on the building regulatory system. However, to describe its framework a wider context is analysed for the following reasons: a) strategies and plans on environment and energy establish main goals and actions to minimize the production of greenhouse gases and to prepare for the challenges of climate change; b) building regulations and their control system set and enforce mandatory minimum requirements for the building stock; c) voluntary certification and labelling set requirements above regulatory minimums and prove their enforcement; d) incentive programs and tax benefits give financial support to change the characteristics of the building stock; e) training and technical information increase the capacity of professionals, and finally, f) sensitization campaigns raise public awareness among consumers and contribute to changes in their behaviour. The results are that there is a coordinated set of initiatives to improve environmental performance of buildings. The initiatives to improve environmental performance of buildings are intended to: change the characteristics of the existing building stock, improve the performance level set for new buildings, and encourage more responsible environmental behaviours. Energy is the resource on which more initiatives were focused. Some initiatives set mandatory command and control regulations but most of them are incentives for voluntary improvements. Despite the numerous initiatives to improve environmental performance of buildings, their actual implementation and effectiveness must be assessed.

Keywords:

building regulations, Portugal, climate change

1 Introduction

Climate change has been recognized as one of the greatest environmental, social and economic threats that the planet and humanity face today. The answer to this problem represents a double challenge: to adopt measures that minimize causes of the problem derived from human activities (mitigate climate change) and to prepare society to deal with the biophysical and social-economic impacts of climate change (adapt to climate change).

It is well-known that buildings are of great importance in the consumption of environmental resources and in the production of greenhouse gases (GHG). Therefore in compliance with international commitments, several legal initiatives to improve environmental performance of buildings were adopted in Portugal, in recent years. The construction sector has also developed initiatives complementary to official ones. As a result, the set of regulations, certification systems, tax exemptions, incentive programs, training courses, technical information, knowledge dissemination and awareness campaigns aimed at contributing to improve the environmental performance of buildings is particularly complex.

This paper presents an analysis of the main initiatives implemented in Portugal to improve the environmental performance of buildings construction and operation. In this context the research questions addressed are as follows:

- 1) What are the guidelines set by national and local strategies and plans?
- 2) What are the environmental provisions set in the regulatory framework?
- 3) What are the voluntary certification systems oriented to construction products and buildings?
- 4) What are the incentive programs and tax benefits?
- 5) What were the recent training programs and awareness initiatives?

Answering these questions provides an overview of the modifications carried out in the Portuguese building regulations and control due to the challenges of climate change. The results may be useful for decision takers, stakeholders, technicians and the general public.

The following section explains the research methodology. The results are presented in sections 3 to 7, which deal with plans and strategies, regulatory and control instruments, voluntary certification and labelling, incentive programs, tax benefits and, finally, support and information. Section 8 describes and discusses the conclusions.

2 Research methodology

Key documents with provisions relating to environmental performance of buildings were collected. Summaries presented for each topic were based on the analysis of information collected. Final conclusions bring together and discuss the partial results.

The study addressed the building regulatory system, though a wider context was analysed in order to describe its framework. The following types of documents were considered relevant to the study due to the reasons mentioned hereafter:

- 1) Strategies and plans on environment and energy set guidelines for the production and review of the regulatory framework.
- 2) Building regulations set minimum quality requirements and the building control system guarantees the enforcement of these requirements.
- 3) Voluntary evaluation and certification systems of the environmental performance of buildings are intended to guarantee levels above the minimums set by building regulations.
- 4) Incentive programs and tax benefits support the implementation of some provisions set by technical building regulations.
- 5) Training courses provide competencies to technicians who apply the building regulations and awareness campaigns raise society's consciousness to environmental problems and thus foster willingness to comply with building regulations.

Environmental resources analysed were energy, water, materials and waste. These resources were selected due to the impact that, in Portugal, construction and use of buildings has on their production and consumption, as described below:

- 1) Buildings account for 30% of total primary energy consumption and for 62% of power consumption. Therefore, the reduction in energy consumption and use of energy from renewable sources in the building sector are measures to reduce both the energy dependency of Portugal from foreign sources and the emission of GHG (Isolani, 2008).
- 2) The urban sector accounts for 9% of total water consumption (industry for 5% and agriculture for the remaining 86%), but represents 46% of the associated cost. In the urban sector, domestic consumption accounts for 45%, commercial consumption for 9% and public consumption for 6%. The remaining 40% are losses due to inefficiency of the system. As water is a limited, structural and strategic natural resource, to reduce consumption through efficient use and the minimization of waste, particularly in the urban sector, are measures with environmental and economic gains for the country (INAG, 2010).
- 3) It is estimated that the construction sector is responsible for more than 50% of waste generated. The flow of waste from construction and demolition has special features which hamper its management, in particular, the heterogeneous constitution with fractions of different sizes and different levels of dangerousness. In addition, construction activity presents itself some specifics, such as, it is geographically dispersed and the works have a temporary nature, which make it difficult to control and monitor the environmental performance of industry (PCS, 2011).

3 Plans and strategies

Portuguese national policies on environment and energy are closely articulated and both are integrated in the national strategy for sustainable development. These policies are formalized in a set of national strategies and plans for various areas. The main changes in the buildings regulatory system introduced to improve the environmental performance of buildings arise from guidelines and actions set in these strategies and plans. Therefore, in this section, we present a summary of the main strategies and plans that enclose guidelines and actions for buildings.

The "National Strategy for Adaptation to Climate Change"¹⁷⁵ sets guidelines to prepare Portugal for the challenges of climate change. At the level of urban planning, the protection of buildings against extreme climatic conditions is identified as a priority. The measures set out in the "National Programme for Climate Change"¹⁷⁶ for buildings focus on improving energy efficiency as a way to reduce GHG emissions.

The "National Strategy for Energy 2020"¹⁷⁷ aims to reduce dependence on foreign energy as well as to cut GHG emissions. The priorities set for buildings are to improve their energy efficiency and to increase the decentralized energy production from renewable sources. Urban regeneration is seen as an opportunity to improve the energy efficiency of the existing building stock. The "National Action Plan for Energy Efficiency"¹⁷⁸ sets actions to enforce the priorities set by the national strategy, including actions to increase energy efficiency and production from renewable sources in buildings. To promote the implementation of these actions, the action plan establishes the creation of incentive programs, tax benefits and awareness campaigns.

The "National Water Plan"¹⁷⁹ sets guidelines for integrated water management. Although specific guidelines for buildings are not included, some general actions aimed at raising public awareness about the environment and water and to promote users participation are set. The "National Programme for the Efficient Use of Water"¹⁸⁰ includes 50 actions applicable to the urban sector, but the 12 actions selected to be implemented in a first phase do not directly apply to buildings.

The "General System for Waste Management"¹⁸¹ provides the framework for waste management and aims to ensure an adequate prevention, recycling and recovery. Specific plans are being enforced for managing specific types of waste, but no plan applies specifically to buildings. However, the "Solid Waste Strategic Plan"¹⁸² sets actions for public awareness, for support of research and for certification of recycled products. The "National allocation plan of emissions"¹⁸³ limits GHG emissions from facilities producing some types of building materials used in buildings.

In September 2009, 118 municipalities and 21 parishes in Portugal had a Local Agenda 21 (GEA, 2011). The local agendas are an action strategy for sustainable development. Though resulting from the community participation, in general the local agendas apply at a local level most of the guidelines set out by national strategies for environment and energy. In this sense, the actions set out in local agendas, which apply to buildings, regard mainly energy.

In May 2011, 59 Portuguese municipalities had joined the "Covenant of Mayors" and 6 of these had submitted a sustainable energy "Action Plan" (CMO, 2011). The action plan outlines how a municipality intends to reach its CO₂ reduction target by 2020. Most actions are aimed at

¹⁸¹ Decree-Law no. 178/2006. OJ (PT) no. 171, 5 September 2006.

¹⁸² Ordinance no. 187/2007. OJ (PT) no. 30, 12 February 2007.

¹⁸³ Resolution of the Council of Ministers no. 1/2008. OJ (PT) no. 3, 4 January 2008.

increasing energy efficiency and use of renewable energy sources. The actions that apply to buildings can be grouped into: renovating buildings, tax incentives, awareness campaigns, counselling services, awards and certification of performance (Cascais Energia, 2010; CMA & AGENEAL, 2010; Vieira et al., 2010). The action plans of Lisbon and Porto, the two major cities, were based on local energy matrixes and also include actions relating to water, materials and waste (Lisboa E-nova, 2008; AdEPorto, 2009).

4 Building regulations and control

In every European Union (EU) country there is a building regulatory system encompassing the building regulations and the building control system. Building regulations set minimum quality requirements to ensure that buildings are safe, healthy, energy-efficient and accessible to everyone who lives and works in and around them. Building control aims to guarantee the application and enforcement of these minimum requirements. In this section, we present a summary of the main building regulations with provisions on the environmental performance of buildings and an analysis of the relevant building control systems.

4.1 General building Code

In Portugal, there is no single Building Act that serves as a legal basis for building regulations and procedures, and defines duties and responsibilities of parties involved in construction. The "General Building Regulation" is the main national building regulation, but there are more than 45 national building regulations and other regulatory documents that focus on specific requirements. There are also local building regulations that complement national ones.

The "General Building Code"¹⁸⁴ has been in force since 1951 and, despite several amendments, no fundamental revision has been approved. This regulation sets out general provisions for building, regarding construction, health, safety and aesthetics. No demands concerning energy saving or environmental protection are included. The 2006 proposal to review the "General Building Code" included general requirements on energy saving and environmental protection. However, the proposal was not implemented.

4.2 Energy

The "Regulation of the Thermal Behaviour Characteristics in Buildings"¹⁸⁵ sets provisions so that: a) requirements of thermal comfort and ventilation, as well as hot water needs, can be met without excessive consumption of energy, and b) pathological situations in building components caused by either surface or internal condensation are minimized. This regulation applies to design of new residential buildings and office buildings without centralized climate control system systems. It also applies to major alterations of existing buildings (i.e., alterations that amount to more than a quarter of the value of an identical model building).

The "Regulation of Energy Systems and Air Conditioning of Buildings"¹⁸⁶ sets rules for designing office and residential buildings with centralized climate control systems, which, in

¹⁸⁴ Decree-Law no. 38382. OJ (PT) no. 166, 7 August 1951.

¹⁸⁵ Decree-Law no. 80/2006. OJ (PT) no. 67, 4 March 2006.

¹⁸⁶ Decree-Law no. 79/2006. OJ (PT) no. 67, 4 March 2006.

addition to requirements related to the built envelope and the limitation of energy consumption, also covers the efficiency and maintenance of those systems.

A special management system has been set for facilities that have an intensive consumption of energy. Its aim is to promote energy efficiency and monitor energy consumption.¹⁸⁷

4.3 Water

The "Regime of Design, Installation and Operation of Public and Building Systems of Water Distribution and Sewerage"¹⁸⁸ sets general principles to be met by these systems and aims to ensure their proper overall functioning, preserving the safety, public health and users convenience. The "General Regulation of Public and Building Systems of Water Distribution and Sewerage"¹⁸⁹, sets the technical standards to be met by the design, construction and operation of these systems, and their standards of hygiene and safety.

None of these regulations include provisions to promote the efficient use of water. On the contrary, the regulation prohibits the existence of distribution networks in dwellings of non-drinking water, which inhibits the use of rainwater and the reuse of domestic wastewater (Pedroso, 2009).

4.4 Types of materials and waste

Portuguese legislation on waste is highly complex and is frequently updated. The main legislation in force and applicable to buildings is the following:

- 1) The "Regime of Construction and Demolition Waste Management"¹⁹⁰ sets rules for the management of waste resulting from construction or demolition of buildings, including its prevention and reuse, as well as the collecting, transporting, storing, sorting, treatment, valorisation, recovery and disposal operations.
- 2) There are "Limitations on Marketing and Use of Dangerous Substances and Preparations"¹⁹¹ that safeguard human health and the environment. Several materials used in buildings are covered by these limitations.
- 3) There are procedures for "Removal of Asbestos in Public Buildings and Facilities"¹⁹² and rules for "Protection of workers from the risks of exposure to asbestos during work"¹⁹³.
- 4) There are rules for the disposal of used PCBs in order to ensure their complete destruction.¹⁹⁴ PCBs are present in some building materials (e.g. plastic inks, hydraulic fluids and climate control systems, adhesives and wood treatment products).
- 5) The "Trading System for Greenhouse Gas Emissions within the European Union"¹⁹⁵ limits GHG emissions of each facility for the 2008-2012 period. Some industrial

¹⁸⁷ Decree-Law no. 71/2008. OJ (PT) no. 74, 15 April 2008.

¹⁸⁸ Decree-Law no. 207/94. OJ (PT) no. 181, 6 August 1994.

¹⁸⁹ Decree-Law no. 23/95. OJ (PT) no. 194, 23 August 1995. With amendments.

¹⁹⁰ Decree-Law no. 46/2008. OJ (PT) no. 51, 12 March 2008.

¹⁹¹ Decree-Law no. 264/98. OJ (PT) no. 28, 9 February 2011.

¹⁹² Law no. 2/2011. OJ (PT) no. 190, 19 August 1998. With amendments.

¹⁹³ Decree-Law no. 266/2007. OJ (PT) no. 141, 26 July 2007.

¹⁹⁴ Decree-Law no. 277/99. OJ (PT) no. 170, 23 July 1999.

¹⁹⁵ Decree-Law no. 233/2004. OJ (PT) no. 291, 14 December 2004. With amendments.

facilities that produce building materials are listed. These facilities belong to the following sectors: ferrous metals; cement; lime; glass; bricks, roof-tiles & accessories; and wall & floor tiles.

Complementary, to inform consumers, there are mandatory rules for the labelling of products that have an impact on energy consumption.¹⁹⁶ The labels and technical specifications provide information on the consumption of energy and other essential resources.

4.5 Bylaws

Local authorities can approve building regulations and set fees on construction works. These regulations contain additional provisions to national ones and deal with subjects of municipal competence and local traditions and uses. Some local building regulations set bylaws with requirements concerning energy saving and environmental protection (e.g., Lisboa, Almada and Cascais municipalities).

4.6 Building control

The "Regime of urbanization and construction"¹⁹⁷ sets the rules of public control over construction works in order to ensure the public interests. According to their category, construction works can either be exempted from building permit procedures or follow a building notice procedure or a regular procedure. Since it has been in force, this regime has been amended 10 times drawing on experience gained by its application to date.

In the sixth amendment, the compliance with the "Regime of Construction and Demolition Waste Management" became compulsory.¹⁹⁸ In the tenth amendment, the installation of photovoltaic solar panels, wind generators and solar heating panels for domestic hot water was exempt from building permit procedures, for simplification purpose. These construction works are not exempt in listed buildings.¹⁹⁹

The "National System of Energy Certification and Indoor Air Quality in Buildings"²⁰⁰ aims to: a) enforce the building regulations on energy performance, b) certify the energy performance and indoor air quality in buildings, and c) identify corrective action or performance improvements for buildings and their energy systems with regard to energy performance and indoor air quality. Within this system:

- 1) A central public agency qualifies and supervises private experts, and approves certificates issued by them.
- 2) Private experts declare the compliance of designs with the regulations for building permit purposes, assess and certify the energetic and indoor air quality performance before the use permit is granted, and analyse and certify the energetic and indoor air quality performance in periodical audits.

¹⁹⁶ Decree-Law no. 63/2011. OJ (PT) no. 89, 9 May 2011.

Decree-Law no. 214/98. OJ (PT) no. 162, 16 July 1998.

¹⁹⁷ Decree-Law no. 555/99. OJ (PT) no. 291, 16 December 1999. With amendments.

¹⁹⁸ Law no. 60/2007. OJ (PT) no. 170, 4 September 2007.

¹⁹⁹ Decree-Law no. 26/2010. OJ (PT) no. 62, 30 March 2010.

²⁰⁰ Decree-Law no. 78/2006. OJ (PT) 4 April.

- 3) The central government supervises the system.

Since 2007 more than 300,000 certificates of energetic and indoor air quality performance have been granted in the scope of the national system of energy certification.

The "Regulation of the Thermal Behaviour Characteristics in Buildings"²⁰¹, the "Regulation of Energy Systems and Air Conditioning of Buildings"²⁰² and the "National System of Energy Certification and Indoor Air Quality in Buildings"²⁰³ partially transpose into the Portuguese legislation the European Directive on the Energy Performance of Buildings (EPBD) adopted in 2002.²⁰⁴ Presently, these regulations and the system are under revision and will probably include the objectives set by the EPBD recast.²⁰⁵

5 Voluntary certification and labelling

Consumers are becoming more concerned about the environment. Therefore, they want to play an active role in the protection of the environment by choosing products that inflict less damage upon it. However, they are bewildered by and sometimes sceptical about the environmental claims made by manufacturers and retailers for their products. Eco-labels are 'brands' placed on certain products that help consumers to choose products, which have been recognised as less harmful to the environment. Eco-labels are voluntary schemes based on specific environmental criteria.

In several countries, specific eco-labels have been developed for buildings. Green building assessment and certification systems comprise a set of criteria, organized in categories, which assess different environmental aspects of buildings. Certification is granted, usually by levels, if certain performance thresholds are reached. Existing systems are voluntary since the belief is that construction sector adherence will be due to environmental commitment or to ensure buildings competitiveness and differentiation.

In this section, we present a summary of the certification and labelling systems available in Portugal for environmental performance of construction materials and buildings.

5.1 Eco-labels

Several eco-label systems are used in Portugal for construction products. The water efficiency of products that consume water (e.g. toilets, showers and taps) may be certified by the ANQIP system (ANQIP, 2011). The certification of solar thermal equipment by the Portuguese Quality System (Certified Product or Solar Keymark), is a necessary condition for State incentives being granted (ADENE et al., 2003-2011). There is the Portuguese system for certification of sustainable forest management, which is recognized by PEFC International (PEFC, 2010). Some products bear the EU Ecolabel, in particular products that fall into the following categories: hard

²⁰¹ Decree-Law no. 80/2006. OJ (PT) no. 67, 4 March 2006.

²⁰² Decree-Law no. 79/2006. OJ (PT) no. 67, 4 March 2006.

²⁰³ Decree-Law no. 78/2006. OJ (PT) 4 April.

²⁰⁴ Council Directive no. 2002/91/EC of 16 December 2002 on the energy performance of buildings OJ (EU) L 1/65 of 4 January 2003.

²⁰⁵ Directive 2010/31/UE of the European Parliament and the Council of 19 May 2010 on the energy performance of buildings (recast). OJ (EU) L 153/13, of 18 June 2010.

floor coverings, heat pumps, paints & varnishes, and lightbulbs (Eco-label, 2002). Several products and construction materials sold in Portugal have marks awarded by international certification systems.

5.2 LiderA

"LiderA" is an assessment and acknowledgement system of buildings and built environment sustainability (LiderA, 2011). The system was originally developed in the framework of a Ph.D. in Environmental Engineering. The first version was presented in 2005 and the first certifications were issued in 2007. Based on experience gained with its implementation, a second version was presented in 2009.

The system can be used to assess and certify developments for different uses (e.g. residential, commercial, office and tourism) and applied at different phases, including planning, design, construction, operation and renewal. The evaluation is divided into 6 categories and 22 areas:

- 1) Site and integration: soil, natural ecosystems, and landscape and Heritage;
- 2) Resources: energy, water, materials and food production;
- 3) Environmental loadings: wastewater, atmospheric emissions, waste, noise emissions, and thermal and light pollution;
- 4) Environmental comfort: air quality, thermal comfort, and lighting and acoustics;
- 5) Socioeconomic experience: access for all, economic diversity, amenities and social interaction, control and participation, and life cycle costs;
- 6) Sustainable use: environmental management, and innovation.

Results of LiderA are presented in a seven level scale (A to G), in which level E is the common practice. There are also classes for developments that undertake structural improvements (A+ and A++) or are regenerative (Class A+++). If the result is above level D, the building or built environment may be certified. Less than 20 developments have been recognized (design phase) or certified (work and operation phase) by LiderA until 2011, but they cover various types of developments: houses, apartment buildings, residential developments, resorts, schools, hotels, office buildings and commercial buildings. Buildings certified by LiderA are granted tax benefits or fee reductions, by some local authorities.

5.3 SBTool^{PT}

"SBTool^{PT}" is a system intended to assess and certify the sustainable performance of buildings and projects (SBTOOL-PT, 2011). It is based on the international system SBTool (Sustainable Building Tool) developed by iiSBE (International Initiative for the Sustainable Built Environment) in collaboration with a consortium of teams from over 20 countries (Europe, Asia and America). The SBTool^{PT} was adapted to Portuguese context by iiSBE Portugal in collaboration with University of Minho and Ecochoice.

The system can be used to assess different types of buildings (e.g. office, residential, or other). It is divided into 3 dimensions, which cover 9 categories and 30 parameters. The 3 dimensions are subdivided into the following categories:

- 1) Environmental dimension: climate change and outdoor air quality, biodiversity, energy, material use and solid waste, and use of water and wastewater;

- 2) Social dimension: comfort and health of occupants, accessibility, and awareness and education for sustainability;
- 3) Economic dimension: life-cycle costs of buildings.

The values of each parameter are converted into a scale with six steps from "E" (conventional practice) to "A+" (best practice). The combination of partial results is done by a weighted average of the values of each parameter. The results are presented on two levels: a profile with the performance of the solution in different categories and an overall score of sustainability. With the exception of two case studies, the information available about the system does not report its application to other developments.

5.4 DomusNatura

"DomusNatura" is a system intended to certify the sustainable performance of developments. It was developed by SGS Portugal and presented in 2008 (SGS SA, 1997-2011). This system aims to combine quality, environment and effective management of resources. The goal is to increase comfort and reduce running costs.

The DomusNatura includes a quality certification entitled DomusQual, which aims to monitor compliance with all legal requirements, regulations and the regulatory compliance and quality construction technique applicable to the project. DomusNature combines the quality factor of DomusQual with good environmental, social and economic performance. DomusNatura system is divided into 6 categories and 127 parameters, of which 21 belong to DomusQual. The 6 categories are:

- 1) sustainable location and safety;
- 2) rational use of water;
- 3) energy and air pollution;
- 4) materials and resources;
- 5) quality and comfort;
- 6) innovation and ecology.

Buildings that meet a certain environmental, social and economic performance are granted a certificate. The level of the certificate is determined according to scores achieved in various parameters. The information available indicates that this system has not been applied up to 2011.

5.5 BREEAM, LEED and Bilan Carbone

Some consulting firms on environmental sustainability are qualified or certified to implement the international environmental certification systems BREEAM, LEED and *Bilan Carbone*. According to available information, the application of these systems in Portugal is uncommon.

6 Incentive programs and tax benefits

In order to reduce consumption and improve environmental performance it is necessary to change the characteristics of the building stock, whether through interventions in the physical envelope of buildings or through the acquisition of more efficient equipment. These changes require a financial investment that it is important to encourage. Incentive programs and tax

benefits can be used for this purpose. In this section we present a summary of the main incentive and programs tax benefits used in Portugal to help improving the environmental performance of buildings.

There are several specific incentive programs to promote the efficient use of energy, to decentralize power production using renewable sources,²⁰⁶ and to encourage the use of solar energy to heat water (ADENE et al., 2003-2011). Other programs pursue these objectives specifically in residential buildings (RE.NEW.ABLE et al., 2011), in buildings from small companies (QREN, 2010), and in non-profit private organizations (InAlentejo, 2010). Some general programs that give financial support to residential buildings renovation can also be used to finance construction works for improving the environmental performance of buildings.²⁰⁷ Within these programs, subsidized loans or non-repayable funds are granted. Incentives for buildings renovation contribute, indirectly, to a reduction of materials consumption and waste production. If energy is produced by private individuals, the public network will take the energy (up to a defined limit) at a guaranteed and advantageous sale price.²⁰⁸

There are funds to support projects that contribute to the efficient use of energy²⁰⁹ and to the reduction of GHG emissions.²¹⁰ Funds are financed with state budget allocations and revenues from fees and fines on energy issues.

Tax reductions are granted for the purchase of properties with high energy efficiency (i.e. 10% increase in the tax deduction for costs with housing loans, if the house is awarded an energy class A or A+ by the national system of energy certification)²¹¹ and of equipment to produce thermal and electric energy from renewable energy sources (i.e. VAT at an intermediate rate of 13%)²¹². To counterbalance the impact of energy inefficient light bulbs on the environment, there is an additional tax on these light bulbs.²¹³

Some local authorities adopt measures similar to those identified at national level, including tax benefits (e.g., reduction in property tax and reduction in fees over construction works) and funds to support local projects (e.g., municipal energy efficiency fund).

7 Training, information and public awareness

To improve the environmental performance of buildings, it is not only necessary to adopt effective policies in terms of regulations and investment, but also to promote a change in

Ordinance no. 26/2011. OJ (PT) no. 6, 10 January 2011.

²¹⁰ Decree-Law no. 71/2006. OJ (PT) no. 60, 24 March 2006.

²¹¹ Decree-Law no. 442-A/88. OJ (PT) no. 277, 30 November 1988. With amendments (Law no. 55-A/2010. OJ (PT) no. 253, 31 December 2010).

²¹² Decree-Law no. 394-B/84. OJ (PT) no. 297, 26 December 1984. With amendments (Decree-Law no. 102/2008. OJ (PT) no. 118, 20 June 2008).

²¹³ Decree-Law no. 108/2007. OJ (PT) no. 72, 12 April 2007.

consumer behaviour, increase the technical capacity of professionals and stimulate the update and progress of scientific knowledge. In this section, we present a summary of the main actions regarding support and information carried out in Portugal to help improving the environmental performance of buildings.

Public sector plays an active role by adopting measures to improve the environmental performance of buildings. For example, a "Strategy for the green public procurement"²¹⁴, a "Program for energy efficiency in public administration"²¹⁵ and a "Regime for public procurement of energy services"²¹⁶ have been approved.

There are training programs on sustainable construction for the different agents in the construction sector. For example, universities and professional associations organize postgraduate courses on sustainable construction for designers, training on building regulations concerning of energy performance of buildings is mandatory to experts qualified under the "National System of Energy Certification and Indoor Air Quality in Buildings", and there are training courses for installers of renewable energy and water use equipment.

Demonstration buildings have been built to show both the potential and the feasibility of new architectonic, technological and construction solutions, which improve the environmental performance of buildings (e.g. *Aveiro Domus*²¹⁷, *Solar XXI*²¹⁸). The buildings are also used to study and monitor the performance of new systems and products.

Frequently, campaigns to raise public awareness for environmental challenges are conducted. The campaigns are promoted by central authorities, local authorities, service providers and non-governmental organizations (NGO's). Some consumer protection and nature conservation NGO's develop information and public awareness projects to encourage a more moderate consumption of resources and to demonstrate how to make daily consumption more efficient (e.g. *Ecocasa*²¹⁹, *Biosfera*²²⁰).

Some local authorities have counselling services for citizens on methods to reduce consumption on a daily basis and on construction works to improve the performance of buildings. Several simulation tools are available online that enable users to characterize their home and lifestyle, to assess the environmental impacts and to learn from the suggestions made by the system. Such tools are usually provided by NGOs (e.g. *DECO*²²¹, *Quercus*²²²) or service providers (e.g. *EDP*²²³, *EPAL*²²⁴).

Abundant technical documentation on sustainable construction adapted to the Portuguese context has been published. Some manuals on sustainable construction are geared towards technicians and others to consumers. To update knowledge of professionals, technical magazines are regularly published on sustainable construction as a whole or on specific aspects. On the Internet, some sites are dedicated solely to disseminate information on good practices in sustainable construction and rehabilitation. In addition, sustainable construction is an issue that arises repeatedly in the general technical documentation of the construction sector.

National Awards are granted to recognize buildings for their sustainability performance, and companies for their energy efficiency practices.

Meetings on sustainable construction are held frequently, and there are numerous research and development projects on sustainable construction.

8 Conclusions and discussion

8.1 Synthesis of results

8.1.1 Guidelines set by national and local strategies and plans

Strategies and plans set goals and actions for an adequate management of energy, water, materials and waste in the context of climate change and sustainable development. The actions established in national strategies and plans that apply to buildings are mainly focused on increasing energy efficiency and energy production from renewable sources. The strategies and plans also include measures aimed at raising awareness and mobilizing citizens to adopt a more responsible environmental behaviour, including moderating or reducing the consumption of water and energy and promoting recycling. Almost 40% of Portuguese municipalities have a Local Agenda 21 for sustainable development and 20% of them joined the "Covenant of Mayors". These figures reflect a growing commitment of local governments with the implementation of the EU and national policy for environment and energy. Although the commitment of municipalities is voluntary it is framed and encouraged by EU policies aimed to the local level.

8.1.2 Environmental provisions set in the regulatory framework

The "General Building Code" does not set the general requirements on energy saving and environmental protection. There was a positive development in building regulations on energy efficiency and indoor air quality. The national system of energy certification has contributed to a better compliance with energy regulations. Building regulations do not include provisions on efficient use of water. Several separate building regulations set provisions on use of dangerous substances, waste from construction or demolition and labelling of products that have an impact on energy consumption. No changes were introduced in the building regulations in order to meet the need to increase protection against extreme weather conditions. Most changes in the building regulations regarding energy and materials were due to the transposition of European directives into the Portuguese legislation.

8.1.3 Voluntary certification systems available for construction products and buildings

There are Portuguese eco-label certification systems for some products and materials (e.g. products that consume water, wooden products, and solar thermal equipment). The EU Ecolabel is also being used for other products. Several products and construction materials sold in Portugal have marks awarded by international certification systems.

There are three systems of green building assessment and certification especially adapted to the Portuguese context, but only one has had some minor applications. International systems of green building assessment and certification can also be used in Portugal, but their implementation is also insignificant. Therefore, adherence to date of the construction sector to green building assessment and certification systems is reduced. Even the tax benefits and fee reductions granted by local authorities seem to be insufficient to boost the application of these systems.

8.1.4 Incentive programs and tax benefits

Although all measures foreseen by plans and strategies were not implemented, there is a wide range of incentive programs to encourage rational use of energy in new and existing buildings. These programs cover up the main types of private buildings: residential, small companies, and non-profit private organizations. Renewal of public buildings is being supported by other programs. No incentive programs to promote a better use of water, materials and waste in buildings were identified. However, incentives for buildings renovation contribute indirectly to reduction in material consumption and waste production.

8.1.5 Training and awareness initiatives

There are many initiatives about sustainable construction in order to: ensure the training of professionals (postgraduate and professional courses), raise awareness among consumers (campaigns, counselling, demonstration buildings), produce and disseminate knowledge (research projects, meetings, books, magazines and sites), recognize best practices (awards), and lead change by example (public leadership programs).

8.2 Discussion

As described, in Portugal there is a set of initiatives to improve environmental performance of buildings. These initiatives pursue the objectives set by the policies on environment and energy and are coordinated in plans and strategies organized by resources (energy, water, materials & waste). The initiatives that have been carried out cover the main domains (Table 1): building regulations and control; certification and labelling; incentive programs and tax benefits; as well as training, information and public awareness.

The initiatives to improve environmental performance of buildings aim to: change the characteristics of the existing building stock, improve the performance level set for new buildings, and encourage more responsible environmental behaviours. Thus, some of these initiatives set mandatory command and control regulations (e.g. building regulations and control) but most of them are incentives for voluntary improvements (e.g. some certification and labelling schemes; incentive programs and tax benefits; as well as training, information and public awareness).

Table 12. Initiatives to improve environmental performance of buildings

	Energy	Water	Materials & waste
Plans and strategies	✓	✓	✓
Building regulations and control	✓	✗	✓
Certification and labelling: Products	✓	✓	✓
Certification and labelling: Buildings	✓	✓	✓
Incentive programs and tax benefits	✓	✗	✗
Training, information and public awareness	✓	✓	✓

Energy is the resource on which more initiatives are focused. The enforcement of building regulations on energy performance is ensured by the participation of private experts who check designs compliance and carry out site inspections. Certificates and permits are still granted by central authorities.

Despite the numerous initiatives to improve environmental performance of buildings, questions arise about their actual effectiveness. Therefore, in future studies we intend to analyse the effectiveness and efficiency of these initiatives. Other developments will be the analysis of initiatives concerning the use of soil and the comparison of initiatives carried out in Portugal with the developments operated in other European countries.

Abstract:

Building regulations set minimum requirements for safe, healthy, energy-efficient and accessible buildings. To guarantee that these requirements are applied, a building control system is indispensable. The trend towards a common market for construction products and services justifies gaining a better insight into the building control systems in the European Union (EU). This paper presents a comparison of the building permit procedures adopted in the 27 EU countries. To collect the necessary information, a questionnaire on building regulatory systems was distributed to national experts in each country and the major legal documents were reviewed. The information was organized in thematic tables containing all the countries. The main conclusion is that the organization of a regular building permit procedure is similar in the EU countries. No major differences were found concerning the several steps it takes to get a building permit and to carry out a construction work: pre-consultation, possibility of phasing, submission demands, checks carried out and maximum procedure time for plan approval, possibility and moment to object to a building permit being issued, start of construction works, frequency and moment of site inspections, fees, and completion of construction works. The main differences concern detail aspects in several of these steps. There is one basic type of building permit procedure in countries from continental Europe. The United Kingdom countries are those presenting more deviations from the common pattern. These deviations aim to reduce the burden of administrative aspects, while ensuring good levels of compliance. In the last 10 to 15 years, the dominant trends identified in the building permit procedure were a decrease in the types of construction works submitted to building authorities' control during plan approval, and the reduction in the maximum building permit procedure times. Building authorities' control during the construction phase has remained unchanged. Altogether, there is a movement towards simpler and faster building permit procedures. For the near future, no major changes are expected in the building permit procedures.

Keywords:

building control system, building permit procedure, comparative study, European Union

1 Introduction

In every European country, there is a building regulatory system encompassing the building regulations and the building control system. Building regulations set minimum quality requirements to ensure that buildings are safe, healthy, energy-efficient and accessible to everyone who lives and works in and around them. Building control aims to guarantee the application and enforcement of these minimum requirements.

The general characteristics of the building control system in European countries are similar. Designs must be prepared and submitted to an authority that approves its compliance with zoning demands and building regulations. During construction, site inspections guarantee that the structure is built according to design and that it complies with the building regulations. Once construction is complete, a final check is conducted and a completion certificate or a use permit is issued.

However, there are many differences among countries regarding procedural aspects of building control. The purpose of this paper is to compare the building permit procedures in the European Union countries. The three research questions addressed are as follows: What are the main differences and similarities? What are the main types of building control systems? What are the main trends and developments?

Studying the building control systems adopted by EU countries is important for three main reasons. Differences among the building control systems of EU countries represent a barrier to the freedom of movement of services in the construction industry. In recent years, there has been a trend towards the gradual privatization of building control in the EU countries, but the extent and the way each country has implemented reforms varied. There are more specialized building regulations and less public resources available for their enforcement, and therefore, more efficient and effective building control systems are required.

The following section explains the research methodology and Section 3 presents the results of the comparative analysis. Section 4 describes and discusses the conclusions of the comparison.

2 Methodology

The research presented in this paper was conducted as part of a European comparative research project currently underway at OTB Research Institute for Housing, Urban and Mobility Studies (Meijer and Visscher, 2008). The project aims to describe and compare the building regulation systems of 34 European countries. The main subjects addressed are as follows: organization and formulation of technical building regulations, tasks and responsibilities of agents involved in building control, technical and administrative aspects of the building permit procedure and quality demands imposed on building control bodies.

The analytical framework of the research project was based on a previous study about building regulations in Europe (Meijer, Visscher and Sheridan, 2002). The development of the research

project was divided into two phases. In the first phase, the aim was to describe the building regulation systems of the European countries. Hence, to collect information, questionnaires were sent to national experts in each country. This information was complemented with the analysis of major legal documents. As a result, a draft of a monograph was written for each country. For some countries, the draft was revised by a second national expert. In the second phase of the project, the aim was to compare the building regulation systems of the various European countries in order to identify trends and developments. For this purpose, the information was organized in thematic tables that containing all the countries.

The questionnaire sent to national experts focused on three subjects:

- 1) The scope of technical building regulations that regulate the minimum quality level for buildings (e.g. subjects regulated, formulation of regulations, ministries responsible).
- 2) The building permit procedures: administrative procedures (e.g. categorization of construction works in relation to permit procedures, time limits, phasing of procedures, tasks and responsibilities of actors).
- 3) The quality demands on building control bodies (e.g. education of staff, working methods, traceability).

It is an elaborate questionnaire that addresses technical and procedural issues of the building regulatory system of each country. Therefore experts could skip questions if they were not able to answer then. But, in this case, questionnaires were sent to other experts that were able to provide information for the unanswered questions, until all the required information was gathered. To date, about 50 national experts answered the questionnaire or revised country monographs.

This paper presents results from the second phase of the research project. It is focused on the technical building regulations. The analysis is restricted to the 27 European Union countries. Due to the federal structures of Austria, Germany and Belgium, analyses of each of these countries focuses on a single state, province or region. With regard to the United Kingdom, information was collected for England & Wales, Northern Ireland and Scotland.

Within the second phase of the research project, the tasks and responsibilities assigned to both public and private parties enforcing the building control systems in EU countries, as well as the organization and formulation of technical building regulations in EU countries have already been compared. The results were presented in previous papers (Pedro, Meijer and Visscher, 2009 & 2010).

The conclusions presented in this paper are not definitive, as the necessary information has not yet been gathered and validated for all countries.

3 Comparative analysis

3.1 Types of procedures

According to their category, construction works can be exempted from or follow a building permit procedure, as described below:

- 1) Exemptions: construction works that have to meet the planning demands and the technical requirements but are exempt from the permit procedure.
- 2) Building notice: construction works that have to be notified to the building authority but can be carried out without a building permit.
- 3) Light procedure: construction works that require a building permit but compliance of building design with building regulations is only ensured for part of the technical requirements.
- 4) Regular procedure: construction works that require a building permit and compliance of building design with building regulations is ensured for all the technical requirements.
- 5) Regularization: construction works that have been built without the required building permit or contrary to the terms and conditions specified in the building permit, but may be legalised.

In all EU countries, there is a regular procedure and there are construction works exempt from permit procedure. Building notice and light procedure only exist in some countries. The following combinations of procedures were identified (Table 4):

- 1) Exemptions and regular procedure (e.g. Belgium, Cyprus, Hungary, Romania and Scotland).
- 2) Exemptions, building notice and regular procedure (e.g. Austria, Bulgaria, Czech Republic, France, Italy, Luxembourg, Malta, Portugal, Slovenia, Sweden, Northern Ireland and England & Wales).
- 3) Exemptions, light procedure and regular procedure (e.g. Germany, Lithuania, the Netherlands and Spain).
- 4) Exemptions, building notice, light procedure and regular procedure (e.g. Estonia, Ireland and Slovakia).

If we consider "building notice" and "light procedure" as an identical "simplified procedure", then the combination "exemptions", "simplified procedure" and "regular procedure" is the dominant approach in the EU countries. In some EU countries, there is a specific procedure for the regularization of construction works (e.g. Poland, Northern Ireland and England & Wales).

Table 4. Which types of permit procedures are defined?

	Austria	Belgium	Bulgaria	Cyprus	Czech Republic	Denmark	Estonia	Finland	France	Germany	Greece	Hungary	Ireland	Italy	Latvia	Lithuania	Luxembourg	Malta	Netherlands	Poland	Portugal	Romania	Slovakia	Slovenia	Spain	Sweden	UK - Northern Ireland	UK - Scotland	UK - England & Wales

In Germany, a type approval may be asked for structures built according to the same design at different places (e.g. prefabricated houses). This implies testing the structural stability as well as sound-, thermal-, damp- and fire-proofing, among other tests. Type approval by one federal state is recognized by all the others, so local building authorities are exempt to check, as part of the permit procedure, whether the structure meets the requirements relating to the type approval functions.

In England & Wales, type approval can be granted for all types of construction features that are subject to Building Regulations. It applies to "building types", which is suitable for complete building designs and for standard building modules repeated in different areas, and to "building systems", which is suitable for systems capable of producing a variety of different buildings using standard components and construction details. Type approval covers compliance with the Building Regulations. A design can be submitted for type approval by local building authorities, in conjunction with either a building notice (if applicable) or the regular procedure. Type approval can also be awarded by approved inspectors. Once the application has been passed, the type approved design is registered with the Local Authorities National Type Approval Confederation (LANTAC). This register enables the local authority building control officers to look up and check design approvals. Having a building type or a building system approved means that it can be used without the plan approval happening repetitively all over the country at each site. Only site specific details such as foundation and drainage need local approval.

During the last 10 to 15 years, in the majority of the EU countries, there has been an increase in the number of construction works exempt from control and an increase in the number of

construction works that shifted from a regular procedure to a light or building notice procedure (Table 5). In few countries, no developments were reported (e.g. Cyprus, Denmark, Estonia, Ireland and Romania) or developments were contrary to the general tendency (e.g. Bulgaria, France and Germany). For the near future, no changes are expected in this respect in the majority of the EU countries, but in some EU countries the previous developments are expected to continue.

Table 5. What were the developments regarding the categorization of construction works?
What changes are expected in this respect?

<i>Increasing number of construction works that shift from a regular procedure to a light or building notice procedure</i>	<i>Austria, Belgium, Czech Republic, Germany, Latvia, Lithuania, Portugal, Slovakia, Northern Ireland, England & Wales</i>	<i>Austria, Czech Republic, Latvia, Lithuania, Slovakia, Northern Ireland</i>
<i>No information</i>	<i>Finland, Greece, Hungary, Luxembourg, Malta, Spain</i>	

3.2 Pre-consultation

During pre-consultation, an applicant for a building permit can address the building authority to discuss the intended construction work and ask for information about specific demands that should be taken into account when further developing the building design (e.g. possible use of the lot, allowable building lines, admissible heights, maximum building mass, admissible derogation from rules). Pre-consultation provides designers with thorough information to develop a building at a particular plot and may give developers the certainty that planning demands will remain unchanged during a certain period.

In almost all EU countries, pre-consultation is voluntarily (Table 6). It is regulated by law, takes place frequently, and the tasks and responsibilities of parties involved, the planning demands, as well as the aesthetics and technical requirements are usually discussed. Only in Bulgaria it is obligatory to ask for detailed planning information for certain types of construction works.

In some EU countries, local authorities are bound to agreements or information provided during pre-consultation (e.g. Belgium, Cyprus, Hungary, Italy, Latvia, Portugal and Sweden). In other EU countries, information provided during pre-consultation is accurate and objective. Although advice and opinions about the merits of a proposal are given in good faith, they are not binding to the local authority or the applicant (e.g. Austria, Denmark, France, Malta, the Netherlands and England & Wales).

Usually, pre-consultation is requested to the building authority by the owner of a land parcel or a person authorized by him. However, in some EU countries, someone other than the owner may request a pre-consultation (e.g. Portugal). In such cases, the building authority notifies the owner and other persons with legal rights over the land parcel.

Table 6. What is the status of pre-consultation?

3.3 Planning permit procedure

Control of planning demands (i.e. aspects linked to the use and location of construction works) and technical requirements of the building and the plot may be done in separate or combined procedures. If there is a separate procedure, a distinction between the planning permit and the building permit is usually made.

In approximately half of the EU countries, there is a combined permit procedure for planning demands and technical requirements (Table 7). In these countries, a planning permit is not required before applying for a building permit. Pre-consultation and phasing the procedures can be used to get detailed planning information and reach informal agreements.

In the other half of the EU countries, there is a separate permit procedure for planning demands and technical requirements. A planning permit is the basis for the development of a design, but it does not bind the building authority to grant a building permit, since it only states that designs presented at this phase are in compliance with the planning demands. The planning permit does not authorise the beginning of construction works.

In several countries, some particular situations were found:

- 1) Both a planning permit and a building permit are required, but for certain type of construction works it is possible to combine the permits into one administrative procedure (e.g. Czech Republic).
- 2) A planning permit and a building permit are only required for certain types of construction works (e.g. Hungary and Luxembourg).
- 3) The applicant can voluntarily apply for a planning permit using pre-consultation (e.g. Bulgaria and France).

Table 7. Are there separate procedures for a planning permit and a building permit?

	Austria	Belgium	Bulgaria	Cyprus	Czech Republic	Denmark	Estonia	Finland	France	Germany	Greece	Hungary	Ireland	Italy	Latvia	Lithuania	Luxembourg	Malta	Netherlands	Poland	Portugal	Romania	Slovakia	Slovenia	Spain	Sweden	UK - Northern Ireland	UK - Scotland	UK - England & Wales

Combined	■	■	■		□	■	■	■	■	■		□		■			□	■	■		■			■					
No information											■																		

3.4 Phasing

Phasing the building permit means the possibility to divide the building permit application into phases. This possibility can be particularly useful for complex construction works, since it avoids developing a fully worked out design before the preliminary design has been checked and approved.

In half of the EU countries, it is not possible to apply for a regular permit in several phases (Table 8). In these countries, the division between planning and building permit and a voluntary pre-consultation can be used to phase procedures. Another way to make up for the lack of phasing is the building authority requesting the applicant to send additional information or to carry out small modifications in the building design (e.g. France, Italy, Malta and Sweden). Additional documentation may be delivered within a certain period. This possibility avoids rejecting the application due to lack of documents or simple deficiencies in the design. In France, Romania, Slovenia and Sweden it is logical that phasing the building permit procedure is not foreseen since building authorities do not check technical requirements of a building permit application.

In the countries where phasing is possible, phases concern three different stages of design development:

- 1) Intended use of the lot, zoning aspects and layout of the building (preliminary design).

- 2) Technical requirements (technical design).
- 3) Detailed drawings to be used during construction (construction drawings).

Phase 1) does not apply to countries where there is a separate procedure for a planning permit and a building permit. Depending on the complexity of each particular building work, the building authority, the applicant, or both, can decide to combine phases.

Table 8. Is it possible to apply for a regular building permit in phases?

	<i>Austria</i>	<i>Belgium</i>	<i>Bulgaria</i>	<i>Cyprus</i>	<i>Czech Republic</i>	<i>Denmark</i>	<i>Estonia</i>	<i>Finland</i>	<i>France</i>	<i>Germany</i>	<i>Greece</i>	<i>Hungary</i>	<i>Ireland</i>	<i>Italy</i>	<i>Latvia</i>	<i>Lithuania</i>	<i>Luxembourg</i>	<i>Malta</i>	<i>Netherlands</i>	<i>Poland</i>	<i>Portugal</i>	<i>Romania</i>	<i>Slovakia</i>	<i>Slovenia</i>	<i>Spain</i>	<i>Sweden</i>	<i>UK - Northern Ireland</i>	<i>UK - Scotland</i>	<i>UK - England & Wales</i>
<i>Yes</i>	■		■		■		■	■					■		■		■		■		■		■		■		■	■	■
<i>No</i>		■		■		■			■	■		■		■				■		■		■		■		■			
<i>No information</i>											■				■														

In almost all EU countries there have been no developments regarding the phasing of the regular building permit procedure during the last 10 to 15 years (Table 9). Only in Czech Republic, Latvia, the Netherlands, Slovakia, Scotland there was an increase in the number of phases. For the near future, no changes are expected changes in this respect in the EU countries.

Table 9. What were the developments regarding the phasing of the regular building permit?
What changes are expected in this respect?

	<i>Past 10/15 years</i>	<i>Near future</i>
<i>No developments</i>	<i>Belgium, Bulgaria, Cyprus, Denmark, France, Germany, Ireland, Italy, Luxembourg, Malta, Poland, Portugal, Romania, Slovenia, Sweden, Northern Ireland, England & Wales</i>	<i>Belgium, Bulgaria, Czech Republic, Cyprus, Denmark, France, Germany, Ireland, Italy, Latvia, Luxembourg, Malta, Poland, Romania, the Netherlands, Portugal, Slovenia, Sweden, Northern Ireland, Scotland, England & Wales</i>
<i>Increasing number of phases</i>	<i>Czech Republic, Latvia, the Netherlands, Slovakia, Scotland</i>	<i>Slovakia</i>
<i>No information</i>	<i>Greece, Spain</i>	

3.5 Submission

Submission demands determine the documentation that must be submitted when an application for a building permit is made. In detail, they describe the documents required to process the application and assess the building design (e.g. drawings, specifications, photographs of existing situation, photomontage of proposal, structural calculations and declarations).

In all EU countries, there are statutory submission demands to apply for a building permit (Table 10).

Table 10. Are there statutory submission demands when applying for a building permit?

	Austria	Belgium	Bulgaria	Cyprus	Czech Republic	Denmark	Estonia	Finland	France	Germany	Greece	Hungary	Ireland	Italy	Latvia	Lithuania	Luxembourg	Malta	Netherlands	Poland	Portugal	Romania	Slovakia	Slovenia	Spain	Sweden	UK - Northern Ireland	UK - Scotland	UK - England & Wales

No																													
No information											■	■	■												■				

According to data collected in 2008, general information about building regulations and permit procedures is available through the Internet in all EU countries. Codes, brochures and paper forms can also be downloaded from the Internet. In one third of the countries, electronic intake of a building permit application is already possible by some or all building authorities. Full electronic case handling of the building permit is possible or being implemented in some countries (e.g. Malta, the Netherlands, Portugal, Northern Ireland, Scotland and England & Wales).

3.6 Plan approval

During plan approval, the competent building authority scrutinises the application and consults with other authorities, if the applicant has not already done so. A design auditor may conduct an audit to provide a substantiated opinion regarding the extent to which the design conforms to planning demands and technical requirements. If opinions from other authorities and design auditors are favourable, and if the competent building authority is satisfied, a building permit is granted.

In almost all EU countries, during plan approval it is checked the compliance of the building design with submission, planning and aesthetic demands, as well as with technical requirements (Table 11). The following are exceptions to the rule:

- 1) In Denmark, the technical requirements that the local building authority is required to check depend on the technical complexity of the construction work (e.g. for single family houses only planning demands are checked).
- 2) In France, the compliance with technical requirements is checked for buildings open to the public and very high buildings, and these checks are limited to fire safety and access for disabled people requirements.
- 3) In Portugal, only technical requirements regarding space standards are checked. The compliance of the building design with relevant building regulations is attested to by liability declarations of designers.

- 4) In Slovenia and Sweden, plan approval does not cover the technical requirements of the design.

In some EU countries, it is acknowledged that the level of control depends on several aspects, such as the complexity of construction and the reliability of private actors involved in the application (e.g. the Netherlands).

Table 11. What is checked during the plan approval phase?

	Austria	Belgium	Bulgaria	Cyprus	Czech Republic	Denmark	Estonia	Finland	France	Germany	Greece	Hungary	Ireland	Italy	Latvia	Lithuania	Luxembourg	Malta	Netherlands	Poland	Portugal	Romania	Slovakia	Slovenia	Spain	Sweden	UK - Northern Ireland	UK - Scotland	UK - England & Wales
Submission demands			■	■	■	■	■	■	■	■				■	■	■	■	■	■	■	■	■	■	■	■	■			■

No information	■	■									■	■	■							■							■	■	

In several EU countries, it is explicit that building permit may contain conditions that must be carried out before or during the construction phase (e.g. Cyprus, Germany, Italy, Luxembourg, Malta, Slovakia, Scotland and England & Wales), such as:

- 1) Submitting some drawings and calculations at a later phase.
- 2) Notifying the local authority of the various stages of the construction work in order to ensure the opportunity to carry out site inspections as it sees fit.
- 3) Taking measurements in the completed building to demonstrate compliance with the building regulations.
- 4) Settling that the building must be connected to the services (i.e. water, drainage, electricity and gas) at the expense of the owner.

In some countries it is also stated that dispensation from the requirements of the building regulations may be granted (e.g. Cyprus, Denmark, Germany, Latvia, the Netherlands and Portugal). For instance, in cases of alteration, renovation or conversion of existing building, provisions on design and layout may be relaxed if the authorities are satisfied that the construction work cannot otherwise be carried out without extensive alterations to the building.

This ability to grant dispensations is used for cases where the regulations for the construction of works (usually adapted to new buildings) are considered too severe. The exemptions have to be justified by economic, architectural or other reasons.

3.7 Beginning of construction works

In almost all EU countries, construction works can start after the building permit has been granted by the building authorities (Table 12). The following are exceptions to this rule:

- 1) In Bulgaria and Denmark, construction works may start after granting the building permit. Exceptionally, to allow an early start of the construction, the local authority may grant a partial building permit or special authorization. In this case, the following stages of design are approved as construction progresses, but always before implementing the respective construction work.
- 2) In Italy, Latvia and Portugal, the situation is identical to 1) but the only early construction works allowed are demolition or excavation and peripheral contention of the soil until the level of the lower floor.
- 3) In Finland, the piling of a building's foundations may be carried out before the construction work begins in accordance with the piling plans submitted to the local building authority. Construction works are considered to have commenced when the casting of foundations or the installation of the construction elements of the foundation begins.
- 4) In Northern Ireland and England & Wales, according to the procedure operated by local authorities, the construction work on site may start soon after application, but to receive the full benefit and protection from the regular procedure it is advisable to start the construction works after the notice of approval is received. If the applicant commences a construction work prior to plan approval, he proceeds entirely at his own risk.
- 5) In England & Wales, according to the procedure operated by approved inspectors, the work may start as soon as the initial notice is accepted by the local authority, subject to any arrangements agreed with the approved inspector.

Table 12. When may construction works start?

	Austria	Belgium	Bulgaria	Cyprus	Czech Republic	Denmark	Estonia	Finland	France	Germany	Greece	Hungary	Ireland	Italy	Latvia	Lithuania	Luxembourg	Malta	Netherlands	Poland	Portugal	Romania	Slovakia	Slovenia	Spain	Sweden	UK - Northern Ireland	UK - Scotland	UK - England & Wales

No information	■										■	■	■				■	■							■					

In several EU countries, the applicant, the contractor or the building surveyor must notify the building authority of his intention to start the construction work (e.g. Denmark, Estonia, France, Germany, Ireland, Sweden and Northern Ireland). Usually, the notification must state who is responsible for the construction work (building surveyor) and who is executing it (contractor). In Malta a notification of start-up is only required for medium and large construction works. In Luxembourg, before the construction work begins the topographic services of the local authority must set the alignment of the construction. If the work is interrupted for a long period, a notification must also be presented.

In all EU countries, a building permit expires if construction work is not started within a certain period or is not completed within a certain time from the date the permit was granted. An application to extend the period to start or to complete the construction work can be submitted to the building authority. Beyond a certain limit, a new building permit must be applied for.

3.8 Site inspections

To ensure that the construction work is carried out in compliance with the approved building plans, the building permit and the building regulations, inspections on the building site are conducted by public or private parties (or a combination).

In about half of the EU countries, a building surveyor, the designer or both carry out site inspections and decide on which phases they are required. Usually, a control plan is agreed with the developer. Building authorities carry out site random inspections to supervise construction works (e.g. Belgium, Cyprus, Estonia, France, Portugal and Romania) or choose key stages of construction works to control them (e.g. Bulgaria, Czech Republic, Denmark, Hungary, Italy, Lithuania and Malta).

In the other half of the EU countries, building authorities are responsible for controlling construction works and decide the level of inspection they intend to carry out. The extent and type of control by the building authorities usually depends on the difficulty of each construction work and on the expertise of private bodies that take part. The following possibilities were identified:

- 1) Building authorities assign the control of construction to private parties and agree on a control plan (e.g. Finland, Germany and Sweden).
- 2) Building authorities select key stages to inspect construction works and may undertake any other inspections as deemed necessary (e.g. the Netherlands, Northern Ireland and England & Wales).
- 3) Building authorities carry out random site inspections (e.g. Poland).

In all EU countries, public building inspectors, from building authorities, have right of access to building sites and are entitled to carry out inspections. They can examine construction works and can request explanations and documents. During site inspections, all parts of the construction work can be inspected. Usually, for each examination the public building inspector provides a report. If construction works take place without a building permit or do not comply with the approved design, they can be suspended until the relevant local authority takes a decision regarding demolition or continuation. Should this happen, the developer may be also sanctioned to pay an administrative fine and the relevant indemnities for damages caused.

In most EU countries, major and minor design changes are possible during construction work. Changes that do not concern zoning demands, prescriptions of the building permit or the building's use are minor and can be declared at the end of construction work. For substantial variations, a formal procedure is required before proceeding with construction work.

In several EU countries, a construction log-book to record daily progress of the construction work is maintained. This book must be accessible at the construction site to public building inspectors.

3.9 Completion

Once the construction work has been completed, the building authorities are usually notified (i.e. completion notification). Several documents may be required for completion, such as, the building design with the works actually carried out; reports of site inspections; the construction log book; and liability declarations by the contractor, building surveyor or designer. In these declarations, signatories attest that the construction work has been carried out in accordance with the approved design and, where applicable, changes comply with the applicable legal and regulatory requirements.

In about half of the EU countries, a final site inspection, conducted by the building authorities and other authorities, is required (e.g. Bulgaria, Cyprus, Czech, Republic Finland, Hungary, Luxembourg, Romania and Spain) (Table 13). The purpose of the final site inspection is to verify whether construction works actually carried out comply with the building regulations, the approved building design and the building permit.

In the other half, the building authorities rely on declarations by the private bodies that conducted the building work or the site inspections and they do not perform a final site inspection (e.g. Austria, Denmark, Ireland, Portugal, Slovenia and Sweden). Even if not required, the building authorities may decide to carry out a site inspection. It usually happens when there are deficiencies in the documentation delivered or doubts about the reliability of the agents involved in the construction work.

Table 13. Is a final site inspection conducted by building authorities required?

	<i>Austria</i>	<i>Belgium</i>	<i>Bulgaria</i>	<i>Cyprus</i>	<i>Czech Republic</i>	<i>Denmark</i>	<i>Estonia</i>	<i>Finland</i>	<i>France</i>	<i>Germany</i>	<i>Greece</i>	<i>Hungary</i>	<i>Ireland</i>	<i>Italy</i>	<i>Latvia</i>	<i>Lithuania</i>	<i>Luxembourg</i>	<i>Malta</i>	<i>Netherlands</i>	<i>Poland</i>	<i>Portugal</i>	<i>Romania</i>	<i>Slovakia</i>	<i>Slovenia</i>	<i>Spain</i>	<i>Sweden</i>	<i>UK - Northern Ireland</i>	<i>UK - Scotland</i>	<i>UK - England & Wales</i>
<i>Required</i>		■	■	■				■	□			■					■					■			■				
<i>Not required</i>	■					■			□				■								■			■		■			
<i>No information</i>	■						■			■	■			■	■	■		■	■	■			■				■	■	■

The exception to this division is France, where a final site inspection is only required for buildings open to the public (e.g. hotels, hospitals, housing for the elderly, theatres and shopping centres) and very high buildings (i.e. residential buildings higher than 50 m and all other buildings higher than 28 m).

If satisfied with the final site inspection or with the documentation, which attests that the construction work was carried out in accordance with the approved design, the building authorities may issue or approve a document certifying that the construction work was successfully completed (i.e. a completion certificate) or that it can be used for the intended purpose (i.e. a use permit). In almost all EU countries, it is mandatory to obtain a completion certificate or a use permit after the construction is completed (Table 14). The following are exceptions to this rule:

- 1) In Belgium, France, the Netherlands and Poland a use permit has to be issued before buildings open to the public can be taken into use.
- 2) In Ireland, contractors are responsible for issuing the completion certificate at request of the builder/owner.
- 3) In England & Wales there are two possibilities. In the procedure operated by local building authorities, the applicant may request a completion certificate, provided that the request is submitted with the initial application for plan approval. In the procedure operated by approved inspectors, when the work is completed, the approved inspector must issue a final certificate to the local authority that may reject it.

Table 14. Is a completion certificate or a use permit issued after the construction is completed?

	Austria	Belgium	Bulgaria	Cyprus	Czech Republic	Denmark	Estonia	Finland	France	Germany	Greece	Hungary	Ireland	Italy	Latvia	Lithuania	Luxembourg	Malta	Netherlands	Poland	Portugal	Romania	Slovakia	Slovenia	Spain	Sweden	UK - Northern Ireland	UK - Scotland	UK - England & Wales

Only at request of contractor or owner													■																□	
No information					■						■				■			■												

In almost all EU countries, a building can be taken into use after a use permit or a completion certificate is granted (Table 15). There are some exceptions to this rule:

- 1) In Austria, the building may be taken into use after a notification of completion has been submitted to the municipal authority.
- 2) In Denmark, buildings may not be taken into use without a use permit, but small buildings (e.g. single-family houses) are exempt.
- 3) In France, buildings may be taken into use after notice of the contractor that the construction work is completed, but for buildings open to the public and very high buildings a use permit has to be issued before it can be taken into use.
- 4) In the Netherlands, a use permit is not required, but buildings open to the public may only be taken into use after a use permit is issued.
- 5) In Poland, buildings may be taken into use after the building authority is notified of the completion of the work, but in certain cases a use permit must be obtained.

Table 15. When can a building be taken into use?

3.10 Fees

In all EU countries, the applicant has to pay a fee to obtain a building permit. However, there is a wide range of variety concerning how the value of fee is determined (Table 16). The following combinations of criteria were identified:

- 1) Construction cost (e.g. Denmark, France, Italy, Romania, Slovenia and Spain).
- 2) Construction cost, floor area and type of construction (e.g. Latvia and Lithuania).
- 3) Cubic meters of construction (e.g. Luxembourg).
- 4) Floor area and building use (e.g. Austria and Bulgaria).
- 5) Fixed fee per building use (e.g. Czech Republic, Finland and Poland).
- 6) Fixed fee plus an additional per floor area (e.g. Estonia).
- 7) Fixed fee plus an additional per construction cost (e.g. the Netherlands).
- 8) Fixed fee or floor area, depending on building use (e.g. Ireland).
- 9) Fixed fee or construction cost, depending on floor area and building use (e.g. Northern Ireland).
- 10) Fixed fee plus an additional per duration of construction works and floor area, depending on building use (e.g. Portugal).

Beyond the building permit fee, other fees may be required. There is also a wide range of variety in the EU countries whether fees are required for pre-consultation, submitting an application, site inspections or obtaining the use permits. Furthermore, in some EU countries, there is an additional fee if the building is located in an area without an approved land development plan or if construction works to provide urban services must be carried out (e.g. Portugal and Sweden).

One aspect is identical in almost all EU countries: no building permit is granted and no construction work can be carried out, unless and until the appropriate fee or contribution has been paid.

Table 16. How are fees determined?

	Austria	Belgium	Bulgaria	Cyprus	Czech Republic	Denmark	Estonia	Finland	France	Germany	Greece	Hungary	Ireland	Italy	Latvia	Lithuania	Luxembourg	Malta	Netherlands	Poland	Portugal	Romania	Slovakia	Slovenia	Spain	Sweden	UK - Northern Ireland	UK - Scotland	UK - England & Wales

No information	■									■	■	■											■			■		■	

3.11 Procedure times

In the majority of the EU countries there are fixed procedure times in which the permit has to be issued (Table 17). The building authorities may extend the maximum procedure time for special situations (e.g. listed buildings, buildings located outside the development boundary of a local plan, complex buildings and major cities) in several countries (e.g. Czech Republic, France, Italy, France, Malta, Portugal and England & Wales). In other countries the maximum procedure time may be shorter if designs are certified by a design auditor (e.g. Bulgaria) or if the procedure is operated by approved inspectors (e.g. England & Wales).

For most of these countries, the maximum procedure time ranges from 8 to 12 weeks. Some countries are exceptions to this rule, as follows:

- 1) In Austria, maximum procedure times vary by state.
- 2) In Bulgaria, maximum procedure time is shorter if designs are certified by a design auditor.
- 3) In Estonia and Lithuania, maximum procedure times are short (due to phasing all times might not have been added).

- 4) In Italy and, particularly, in Portugal, maximum procedure times are long, which is a common reason for complaint (one should take into consideration that these are combined procedures) (vd. 3.3).
- 5) In Malta, maximum procedure time is extended if buildings are located outside the development boundary of a local plan.
- 6) In England & Wales, according to the procedure operated by local building authorities, the maximum procedure time is short, which is probably due to the separation between planning and building permit.
- 7) In England & Wales, according to the procedure operated by approved inspectors, the only statutory delays are created by the periods allowed for local authorities to reject the initial notice and the plan certificate.

In the remaining EU countries, no maximum times have been set. The justification for this option is that the time taken can vary considerably depending on the complexity of the construction work, the quality of the application and the use of design auditors.

Table 17. What are the maximum procedure times in which the permit has to be issued?

	<i>Austria</i>	<i>Belgium</i>	<i>Bulgaria</i>	<i>Cyprus</i>	<i>Czech Republic</i>	<i>Denmark</i>	<i>Estonia</i>	<i>Finland</i>	<i>France</i>	<i>Germany</i>	<i>Greece</i>	<i>Hungary</i>	<i>Ireland</i>	<i>Italy</i>	<i>Latvia</i>	<i>Lithuania</i>	<i>Luxembourg</i>	<i>Malta</i>	<i>Netherlands</i>	<i>Poland</i>	<i>Portugal</i>	<i>Romania</i>	<i>Slovakia</i>	<i>Slovenia</i>	<i>Spain</i>	<i>Sweden</i>	<i>UK - Northern Ireland</i>	<i>UK - Scotland</i>	<i>UK - England & Wales</i>
<i>Time is set (in weeks)</i>	8 to 24	11	6 or 11		4 or 8		3 or 6		8 or 12	8		8	12	10 or 18		3		12 or 26	12	9	25 or 31	8		8	8		8		2 or 8
<i>Time is not set</i>				■		■									■		■						■			■			
<i>No information</i>								■			■																	■	

There is not a pattern as to what happens if deadlines are not met (Table 18). The following approaches are adopted in different EU countries:

- 1) The building permit is automatically granted (e.g. Germany, Lithuania, Romania and Spain).
- 2) The building permit is automatically refused (e.g. Belgium, Italy, Northern Ireland and Scotland).
- 3) The applicant can appeal to a higher authority (e.g. Austria, Portugal and Slovenia).
- 4) The applicant has to wait for the decision (e.g. Czech Republic).
- 5) The applicant can claim the dispensation (e.g. Ireland).

Table 18. What happens when deadlines are not met?
(maximum procedure time is not set in shaded countries – vd. Table 14)

	Austria	Belgium	Bulgaria	Cyprus	Czech Republic	Denmark	Estonia	Finland	France	Germany	Greece	Hungary	Ireland	Italy	Latvia	Lithuania	Luxembourg	Malta	Netherlands	Poland	Portugal	Romania	Slovakia	Slovenia	Spain	Sweden	UK - Northern Ireland	UK - Scotland	UK - England & Wales
<i>Permit granted</i>									■	■						■					■			■					
<i>Permit refused</i>		■											■														■	■	
<i>Other</i>	■				■				□				■								■		■						
<i>No information</i>		■					■	■			■	■						■	■	■									■

In France, if the applicant does not receive a response within the maximum procedure time, then the application for the building permit has been approved (i.e. tacit approval). However, in some cases (e.g. building located in a conservation area or a natural park, building subjected to public survey) the applicant cannot assume a tacit approval.

During the last 10 to 15 years, the maximum procedure times have been shortened in several EU countries (e.g. Bulgaria, Czech Republic, France, Germany, Ireland, Lithuania, Portugal and Slovenia). For the near future, no further changes are expected in this respect in most EU countries, with the exceptions of Czech Republic and Lithuania where the procedure times may be extended due to more complicated procedures. When compared with other EU countries, Czech Republic and Lithuania countries have shorter procedure times.

3.12 Objections

In some EU countries, neighbours and other parties have the legal right to object to a building permit or to a planning permit being granted to a construction work. In other EU countries, third parties do not have an automatic right to object, but can provide the building authorities with information that they feel may have a material effect on the outcome of the application. Objections and information must be based on an objective impairment of legal rights or on an infringement of the planning instruments or building regulations. The building authorities take objections and information into consideration for the final deliberation.

In almost all EU countries, objections and information can be presented to the building authorities during the plan approval phase or before the final permit has been issued. In France

the objections must be presented within 2 months after the day when the notice that the building permit was granted is displayed on the property.

To inform third parties, in some EU countries it is mandatory to inform neighbours about an intended construction work (e.g. Belgium and Finland) or to make public the application to a building permit by suitable means (e.g. Italy, Malta, Portugal). In England & Wales, neighbours must only be notified if the construction work is close to or directly affecting the boundary or party wall of a premise. Complementary, in some EU countries a copy of any application for a building permit is available for inspection by the public at the building authorities (e.g. Malta and Portugal) and major construction works may be subjected to a hearing period (e.g. Portugal).

4 Conclusions and discussion

4.1 Main differences and similarities

The organization of a regular building permit procedure is similar in EU countries. The usual procedure includes the following steps:

- 1) During a voluntary pre-consultation, applicants can discuss with the building authorities planning demands, aesthetics and technical requirements.
- 2) Phasing the building permit procedure is possible to avoid developing a fully worked out design before the preliminary design has been checked.
- 3) Statutory submission demands determine the documentation to submit with an application; information about building regulations and permit procedures is available through the Internet.
- 4) During plan approval, the compliance of the building design with submission, planning and aesthetic demands, as well as with technical requirements is checked; plan approval usually takes 8 to 12 weeks.
- 5) Neighbours and other parties can raise objections to a building permit being granted during the plan approval phase or before the final permit has been issued.
- 6) Construction works can begin after the building permit has been granted by the building authorities, but there are strategies to allow an early start of the construction; total or part of the building permit fees must be paid before construction works can be carried out.
- 7) Building authorities must be notified before construction works start; the building permit expires if construction work is not started within a certain period or is not completed within a certain period since the date it was granted.
- 8) Site inspections are carried out to ensure the compliance of construction works with the approved building design, the building permit and the building regulations.
- 9) During construction, minor design changes are possible and can be declared at the end of construction work; for substantial variations a formal procedure is required before proceeding with construction work.
- 10) Public building inspectors are entitled to carry out inspections and if construction works take place without a building permit or do not comply with the approved design, they can be suspended.
- 11) Once construction is complete, a final site inspection is conducted and documentation that attest the compliance with the building design is submitted to building authorities.

- 12) If satisfied, building authorities issue a completion certificate or a use permit; the building can be taken into use after a use permit or a completion certificate is granted.

However, there are several differences between countries concerning detail aspects of the building permit procedure. The following differences were identified:

- 1) Agreements and information provided during pre-consultation are only binding to building authorities in some countries.
- 2) There are different levels of implementation of electronic case handling of the building permit.
- 3) Permit procedures for planning demands and technical requirements may be separated or combined.
- 4) Phasing the permit procedure is only statutory available in some countries; different strategies are used to divide the building permit procedure in phases.
- 5) The right to object to a building permit being granted is only laid down by law in some countries.
- 6) Different criteria are used to allow an early start of construction works.
- 7) The value of the building permit fee is determined by different criteria.
- 8) In addition to the building permit fee, other fees may or may not be required.
- 9) When maximum procedure times are not met by the building authorities different consequences can result.
- 10) A completion certificate or a use permit issued may not be required when the construction is finished.

4.2 Main types

As described above, the organization of the regular building permit procedure is similar in the different EU countries. No substantial differences were found in continental Europe countries.

The United Kingdom countries, and particularly England & Wales, are those that present more deviations from the common pattern. The following distinctive characteristics were identified:

- 1) There is a specific type approval procedure.
- 2) Planning permit and building permit are separated, and there is also the possibility to phase the building permit procedure.
- 3) Full electronic case handling of the building permit is already available.
- 4) The applicant can choose to have plan approval and site inspections conducted by either building authorities or approved inspectors.
- 5) Construction works may start soon after submission of the application, not having to wait for plan approval.
- 6) Maximum procedure times are shorter than the average.

All these characteristics have in common the aim of reducing the burden of administrative aspects, while ensuring good levels of compliance.

4.3 Trends and developments

In the last 10 to 15 years, the dominant trends identified in the building permit procedure were a decrease in the types of construction works submitted to building authorities control during plan

approval, and a reduction of building permit maximum procedure times. Building authorities' control during the construction phase remains unchanged. Altogether, there is a movement towards simpler and faster building permit procedures.

For the near future, no major changes are expected in the building permit procedures.

4.4 Lessons to be learned

The analysis provided a global picture of the building permit procedure of the EU countries. The results can be useful for situating the procedure of each country within the EU panorama, assessing the main trends and developments and guiding strategic choices on possible improvements in each country.

A comparative analysis of the EU countries regarding organization and formulation of technical building regulations, tasks and responsibilities in the building control systems and building permit procedure has been accomplished. To complete this comparative study of the regulatory systems of EU countries, an analysis focusing on the quality demands of public and private building-control bodies is still required. Furthermore, the analysis of regulatory systems should proceed with studies about the performance of each type of system in terms of adequacy, efficiency and effectiveness.

In an overall analysis, many differences were identified in the building permit procedure of the EU countries. These differences constitute a barrier to the free circulation of people and services. Additional uniformity among building permit procedure would contribute to the establishment and functioning of a single market for services in the construction industry, in which designers, developers and builders are no longer limited to working in national markets.

5 Acknowledgements

Thanks are extended to the national experts of the EU countries that filled in the questionnaire on building regulations.

Constructing Corporate Social Responsibility: Encouraging CSR through Legislation and Regulation

Abstract:

This paper reports on the results of a series of interviews with industry leaders in the Australian construction industry, which explored industry perceptions of Corporate Social Responsibility (CSR), along with some of the barriers and facilitators for its adoption in the industry. The Australian construction industry has been accused of being “socially irresponsible” and some have argued that, compared with other industries, the building and construction industry is lagging behind in embracing the new paradigms of environmental sustainability (Fraser 2007). As such, the Australian construction industry is well-positioned to provide an interesting case study of the issues associated with instigating change in relation to CSR. This paper discusses the findings of this pilot research project, with a particular focus on implications for improving CSR in small to medium sized enterprises (SMEs) in the construction industry and what role (if any) can be played by legislation and regulation. The results suggest that a combination of harder legislative measures and softer approaches designed to build on the informal approaches of SMEs, would be appropriate to encourage the development of CSR in the industry.

Australia, construction, Corporate Social Responsibility (CSR), legislation, Small to Medium Sized Enterprises (SMEs)

1 Introduction

This paper reflects on the results of a preliminary research project, conducted at the University of South Australia, on CSR in the Australian construction industry. The project was designed to gauge the current level of understanding of CSR in the construction industry and explore how it was being applied (if at all) in SMEs in the Australian Construction Industry.

The paper begins by describing the background in which this research took place, with particular reference to the current status of CSR in the Australian construction industry. The authors then outline the methodology and results of the research, before embarking on a discussion of the implications of these results. The paper explores how CSR is understood in the industry and

more generally in the research literature in this field. We then discuss the implications of the research findings in terms of the implementation of CSR in the Australian construction industry and what role (if any) can be played by regulation and legislation in encouraging its uptake.

The results suggest that a combination of measures and approaches would be appropriate to encourage the development of CSR in the industry. Such measures might include the introduction of mandatory reporting mechanisms and standards, an industry-wide code of ethics, and business incentives, along with other means of soft-regulation. Attention should also be paid to the clarification and simplification of existing legislation to improve compliance and further encourage CSR in the industry. These measures would be enhanced by informal initiatives designed to capitalise on the preference for informal CSR practices, which may be better suited to an environment populated by SMEs. Such initiatives might include improved education around the concept of CSR, a focus on the role of small business champions for CSR and mechanisms for networking and exchange of information between firms. Further research may assist in determining the best form for such initiatives to take and which are more likely to succeed, as well as enabling a more nuanced understanding of how the applicability and effectiveness of such measures is likely to vary across the states and territories, industry sectors and different size businesses.

2 Literature Review

CSR has proven notoriously difficult to define with multiple understandings of the concept existing in the literature. However, in the context of construction, CSR can be defined as “the commitment to integrate socially responsible values and concerns of stakeholders into their operations in a manner that fulfils and exceeds current legal and commercial expectations” (Constructing Excellence 2004). While acknowledging that CSR is about more than legislation and regulation, this definition clearly indicates that they have a role to play in encouraging CSR in the industry. This paper seeks to explore how this role is currently being played in the Australian context, along with making some suggestions for future improvements.

As argued previously, (Chiveralls et al. 2011) the Australian construction industry has a poor reputation in terms of CSR. A recent study by Lingard et al. (2009: 378) concluded that the Australian construction industry is “fraudulent”, “corrupt” and “socially irresponsible”. With an average of 49 workers having been killed on Australian construction sites each year since 1997, construction is Australia’s third most dangerous industry (Fraser 2007). The Industry has been the subject of two controversial Royal Commissions (Gyles et al. 1992; Cole 2003). The final report of the Cole Royal Commission claimed that the industry was characterised by a pervasive “culture of lawlessness” (Cole 2003). However, this Commission has since been dismissed by some as an anti-union “political stunt” designed to boost the popularity of the then Liberal National Coalition Government (Lingard et al. 2009: 367). Nevertheless, the findings have clearly had an impact on perceptions of the industry, with the industry often being described by outsiders and in the media, as being populated by a bunch of “cowboys”, with no regard for the law (e.g. Bainbridge 2010). As part of the gendered mythology of the industry, it is likely that this image obscures as much as it exposes, as in reality the industry is neither the cowboy hero nor the villain (Miller, 2004).

However, there is evidence that the construction industry may be more socially responsible than it is generally given credence for and, at the very least, is beginning to make improvements in its commitments to CSR. For example, a recent report by the Australian Centre for Corporate Social Responsibility (ACCSR) found that the property development/construction industry recorded a slightly above average CSR budget relative to other industries (ACCSR 2011). It remains uncertain how these figures apply to SMEs and whether they are an accurate reflection of practice on the ground. Nevertheless, the report indicates a growing concern in the industry to improve its CSR performance. It is clear that the performance of the construction industry is crucial in addressing the economic, social and environmental sustainability of Australian cities. This is particularly the case as the pace of urbanisation, resource depletion and pollution increases. The construction industry produces physical infrastructure that alters our natural and built environment and helps to determine the nature, function and appearance of our cities, towns and regional areas, along with contributing to the formation of communities (Robinson et al. 2006; Myers 2005). In the process, it consumes materials and resources, changes the natural and built landscapes, emits pollutants, and impacts on the lives of communities both inside and outside of its structures (van Wyk & Chege 2004).

The industry has the potential to be a significant contributor to sustainability as a major driver of activity in the Australian economy. The building and construction industry made up 6.4 per cent of Australia's gross domestic product in the years 2005-06 with total activity during this period valued at \$95.8 billion dollars, an increase of 13 per cent over the previous year (Zillante 2007). The construction industry also provides employment that underpins social and economic sustainability. In 2006-07, the industry employed 917,600 workers (4.7 per cent higher than the previous year), which represented approximately 8.7 per cent of all employed persons in Australia (ABS 2008). The majority of construction industry employment during this period was in construction trade services (633,500 people or 69 per cent), which includes those engaged in earthmoving, concreting, bricklaying, roofing, plumbing, electrical, carpentry, painting, glazing and landscaping (ibid). However, the above figures are likely to be impacted by the recent contractions in the global economy caused by the global financial crisis. In order to harness its full potential, the industry will need to adapt in order to face new challenges, including addressing the matter of CSR and sustainability.

The performance of the construction industry in terms of CSR and sustainability also has significant implications in terms of environmental impacts as this sector consumes large quantities of energy derived from fossil fuels (Zuo & Zillante 2008). A study by Pricewaterhouse Coopers (2008) estimated that the construction industry accounts for half of all resource usage and up to 40 per cent of energy consumption. This energy is consumed during the whole life cycle, including the construction phase, the operation phase and during the process used to manufacture building materials (Pullen et al. 2006). Other related environmental issues include the reduction of CO₂ emissions, minimizing of construction and demolition waste, and prevention of indoor air pollution (Alnaser & Flanagan 2007).

Due to the significance of the industry's impacts in terms of economic, social and environmental sustainability, there is a considerable need for quality research which explores the barriers and drivers towards the implementation of CSR in the industry across these three dimensions and beyond. We encourage academics of various disciplines to take up this research agenda with some urgency. While a number of studies have already been conducted on CSR in Australia (e.g.

Quazi & O'Brien 2000; Anderson & Landau 2006), few studies have been undertaken to investigate CSR in the construction industry, especially in the Australian context. The majority of these studies focus on ethical behaviour within the built environment (e.g. Bowen et al. 2007; Liu et al. 2004; Suen et al. 2007). While not based on empirical research, there are also other studies which explore CSR from a construction management perspective (e.g. Barry 2003; Barthorpe et al. 2004; Rameezdeen 2007; Wilkinson et al. 2004). While Murray and Dainty (2009) provide a useful overview of the CSR concept in relation to the construction industry, their work is not prescriptive and with the exception of Lingard et al.'s (2009) chapter, is not focused on the specific context of the Australian industry.

As we have argued elsewhere (Chiveralls et al 2011), the structure of the construction industry differentiates it from other industries which may have already progressed down the CSR route. The existing knowledge of CSR in the construction industry mainly comes from studies of large enterprises, many of which have taken action to address social and environmental issues (see Bovis Lend Lease n.d.; Colliers International 2008; Stockland 2008; Jones et al. 2006; Douglas et al. 2006; Petrovic-Lazarevic 2008). However, due to its use of the subcontracting approach, the Australian construction industry is overwhelmingly made up of small to medium sized firms. These SMEs contribute most of the industry's output and account for 99 per cent of the total number of enterprises (RCBCI 2002). As identified by Cole (2003) 36 per cent of all people employed in construction work for subcontractors and of these 94 per cent employ fewer than five employees. Therefore, any overall performance improvement of the industry is significantly influenced by the performance of SMEs and their subcontractors (Sexton & Barrett 2003). Considering the key role SMEs play in the construction industry, it is imperative to investigate how SMEs can be better engaged in the CSR implementation process. This research addresses a significant gap in the literature in exploring current CSR practices in SMEs in the Australian construction industry, and whether these could be improved through legislation and regulation.

3 Research Methodology

This paper reports on the results of a pilot study of CSR in SMEs in the South Australian construction industry. As outlined elsewhere (Chiveralls, 2011) the pilot study involved an extensive literature review, along with the conduct and analysis of 10 semi-structured interviews on CSR with the directors or senior members (as senior as it was possible to arrange) of private sector building construction companies in the South Australian Construction Industry, within suburban and metropolitan Adelaide, which could be considered to be SMEs. While there is no clear definition of SMEs globally, it is generally acknowledged that SMEs employ less than 250 staff (Egbu et al. 2005). Six of the companies interviewed employed less than 50 employees (four of which employed 20 or less at 1, 2, 11 and 20 respectively), two employed between 50 and 100 and two between 150 and 250 employees in SA. However, it is noteworthy that while the rest of the companies operated primarily in SA, the three companies with the highest number of employees in SA, had recently expanded and commenced interstate operations and as a result had more than 250 employees Australia wide (at around 260, 300 and 600 respectively). As such, the team debated over whether they should be included in the sample as SMEs. However, as they employed less than 250 employees in SA and their inclusion provided an opportunity to explore how the expansion of SMEs may impact on their approach to CSR, we determined they should remain in the sample.

This pilot study will be used to gather support for a much larger research project, which we plan to conduct to expand on the limitations of this research. In the future we hope to expand this research across Australia, to enable us to gain a wider picture of experiences in the industry across the nation and explore differences between the states. As this study was subject to limited coverage (located primarily within SA) and duration, findings are preliminary only.

Participants were recruited through snowballing, beginning with contacts from companies known to the School of Natural and Built Environments at the University of South Australia. Participants were contacted via email, provided with an information sheet and consent form about the project and asked if they would be willing to participate in an interview of around one hour's duration at their place of work.

Interviews consisted of around 10 questions on CSR covering topics such as: participants' understanding of CSR; major social impacts of the construction industry; relevance (if any) of CSR for their company, CSR initiatives adopted by their company; effectiveness of initiatives; and barriers, successes and drivers to implementing CSR for SMEs in the South Australian construction industry.

Interviews were noted, transcribed and analysed using the qualitative data analysis program NVivo® to highlight common themes and insights from the interview data. A qualitative approach to the research seemed appropriate, given the limited scope and duration of the project and our desire to explore in-depth the current understandings of industry leaders. While a full analysis of these results is beyond the scope of this paper, the results and discussion presented below focus on the implications of our findings in terms of barriers and facilitators to the implementation of CSR in the Australian Construction Industry and what role (if any) can be played industry regulation and legislation.

4 Findings and Discussion

4.1 Understanding CSR in the Australian Construction Industry

One of the main aims of this preliminary research project was to explore how CSR was currently understood by senior members of SMEs in the industry. As discussed previously (Chiveralls 2011), the results of our preliminary research project suggested that a lack of knowledge and awareness of the concept is one of the main barriers to the adoption of CSR by SMEs in the industry. These results reinforce the findings of the ACCSR (2007) which identified a general lack of awareness of CSR within the organization as one of the main barriers to CSR success. Without exception, every person interviewed expressed some level of confusion over the meaning of the term CSR. When being asked about what CSR meant to them or how they understood the concept, interviewees replied with variations of "I really don't", "I'm not sure", "Well I haven't given it a lot of thought I can tell you" or "I was hoping you might tell me". One participant remarked that when they see the abbreviation CSR they don't think of Corporate Social Responsibility but of a company called CSR Building Materials. Another commented:

After 30 years experience at all levels in my industry, really any thoughts about corporate social responsibility...up until this point in time have never really entered into my head.

Despite obvious levels of uncertainty and an apparent lack of knowledge about the concept, most interviewees seemed eager to discuss the concept and interested to hear about how it might apply to them and the everyday practice of their businesses. Through discussion of examples of CSR initiatives in the companies they worked for and how these related to the wider social impacts of the industry, much of the initial trepidation in discussing the concept was overcome, revealing a more nuanced and complex understanding of the concept than first imagined. On reflecting on the meaning of the term, interviewees provided a wide range of responses, commensurate with the variety of definitions and theoretical understandings of the concept. Participants also described a wide variety of initiatives and practices as falling under the banner of CSR and all participants were able to describe at least one practice in their organisation that they could relate back to CSR. These responses and initiatives will be analysed and discussed in detail in future papers. As discussed in previous papers, our results clearly suggest that a lack of understanding of CSR is contributing to a fragmented and ad-hoc approach to its implementation in SMEs in the Australian construction industry (Chiveralls et al. 2011). However, in this paper, we focus our analysis of research results on the barriers and drivers to the implementation of CSR and what role (if any) can be played by legislation and regulation.

4.2 Improving CSR in the Australian Construction Industry through Formal Regulation

The current state of regulation of CSR in the Australian construction industry can best be described as a state of soft regulation. This approach has accordance with dominant perspectives which view CSR as a primarily voluntary endeavour that should not be allowed to interfere with the other objectives of business (Green 2009). Soft regulation approaches include the establishment of voluntary standards of behaviour and encouragement for voluntary action, for example through social standards such as accountability 8000, the European Corporate Sustainability Framework and the International Standards Organisation's ISO2600 standard on social responsibility published in November of 2010. As pointed out by Lingard et al. (2009), a formal framework for CSR in Australia has been published in the form of Standard AS800302003 (Standards Australia 2003b). The standard forms part of a suite of Australian standards relating to corporate governance, which also includes standards on corporate fraud, corruption control and whistle-blower protection programmes, and is designed to provide guidance for organisations to establish, implement and manage CSR programmes. While the standard references Australian Standard AS8306-1998, which outlines principles for effective compliance programmes to promote compliance with laws and regulations, application of the standard remains voluntary and is unlikely to be widespread in the industry (Lingard et al. 2009).

This contention was supported by our preliminary research findings in that only one of the SMEs involved in the study (the largest in the sample) had an official policy document which mentioned the term and none had official policies dedicated to CSR. A couple of interviewees described CSR practices in the organisation with reference to official policies in other areas (like Occupational Health and Safety [OH&S] and the Environment). For example, one participant stated that he didn't see a need to have Australian standards on CSR because it was already covered by areas like Quality, the Environment and OH&S, which all had Australian Standards which their company utilised. However, the companies that fell into this category were the largest companies in the sample, and most interviewees who expressed support for CSR, tended to describe it as a kind of informal "business culture". Jenkins (2006) also found that SME were

more likely to be characterised by relationships established on a more informal trusting basis and characterised by more personal intuitive engagement. It may be this informal nature which makes SMEs more resistant to regulation and “less inclined to use formal instruments (such as codes of conduct) to foster ethical behaviour within the organisation” (Jenkins, 2006: 243). Accordingly, interviewees seemed resistant to the regulation of CSR, particularly through legislation. In fact, interviewees had a clear preference for CSR to exist as an informal, unwritten practice. There was a general sentiment that the industry was already overregulated. Interviewees expressed fears that legislating CSR would threaten the economic survival of their companies, by restricting their ability to vary participation in CSR according to affordability and viability, as determined by their current financial capacity and stage of business development.

However, interviewee comments with regard to the cause of past improvements in the industry revealed contradictions in their attitudes toward the legislation of CSR. The Australian construction industry has shown that it is capable of significant change, having made improvements across a number of areas in recent years. For example, in the area of OH&S, many construction companies now place a high importance on safety (Bovis Lend Lease n.d.; Mohamed 2002; Fraser 2007). In recent years, further change has been embraced to avoid adversarial relationships and a poor contractual culture, which has resulted in improvements with regard to the effectiveness and competitiveness of the industry (Zuo 2008; RCBCI 2002). Interviewees clearly indicated that they thought legislation and regulation played a key role in motivating these shifts. For example, one interviewee commented, that these changes had resulted from an “Australia-wide politically driven process” which had been “enacted through Parliament” as a “factor of government”. He stated that people were unlikely to implement change unless it became a governance matter but that once legislation was in place “people run with it”. Similarly, another participant commented that a lot of the changes that have happened in the industry occurred because “they’ve been driven by government and social processes”. He stated, “...once it’s been enacted we have been able to respond.” He explained that because of the competitive nature of the industry, which has very small profit margins, “the only way you will get those kind of changes is through policy – so they are required to incorporate it”. However, when asked if he thought there was a similar role for government in legislating CSR, the same participant replied, “No, definitely not. It’s [CSR is] what you want to do.”

Despite the reticence expressed by interviewees, there is a clear role for legislation in improving CSR performance. While Lingard et al. (2009: 378) state that change will only come about through “general cultural and societal moral and ethical change”, they rely on a *laissez faire* definition of CSR, understanding CSR as a voluntary act (2009: 351). Such a “soft” definition of CSR is at odds with their dismal picture of CSR in the Australian construction industry and one might question how successful voluntary adoption would be in this milieu. If the industry is so behind in CSR practices, it would seem that the informal, voluntary approach to CSR is not working, and that government regulated standards are required. Lingard et al. (2009) could go further in their recommendation that all construction firms, public and private, should adopt the Australian Standard on Fraud and Corruption Control, and recommend regulated, mandatory adoption of CSR standards (Standards Australia 2003c). While none of the companies involved in our research project had official policies on CSR, the fact that a couple of the interviewees stated that they could demonstrate formal compliance with CSR principles by reference to other Australian Standards, suggests that the adoption of the Australian Standard on CSR is far from impossible.

Even without the introduction of mandatory standards on CSR, it could be encouraged indirectly through alteration to planning and regulatory requirements in specific areas. For example, the current National Construction Code (ABCB 2011) does not encourage the use of recycled building materials. One suggested policy mechanism to encourage reduction in volumes of construction and demolition waste is the increase of landfill taxes and introduction of reuse subsidies. Another may be the mandated introduction of sorting bins for recycling on construction sites, perhaps backed by government funding or provision. The drive for legislative change is supported by the findings of a study by Zillante and Zuo (2008), which assessed the awareness of small construction firms of waste management systems. The study concluded that there is not enough pressure on firms to create behavioural change. While in the past, legal commitments have mainly been allocated to contractors, research suggests that compulsory measures are necessary to ensure that all project stakeholders play an active role (Tam et al. 2010).

However, there is also an urgent need to tighten and simplify existing legislation and regulation in order to improve compliance and enable improvements in CSR. For example, in 2004, the Australian Government introduced a mandatory regulation for all new homes across the country to have an energy rating of a minimum of three to four stars. Six years later, this compulsory rating has been raised to a minimum of five stars with Victoria, Queensland, South Australia and the ACT having already moved to a six-star rating (Western Australia is due to follow suit next year). However, the star ratings have been found to be potentially misleading, with wide variations in their measurement and results and no research or regulation having been developed to prove that they're accurate (ABC, 2011). Similar difficulties have been reported in relation to establishing compliance with regulation for recycled materials (e.g. Tam 2009). Without uniform enforcement of specific codes, specifications, standards and guidelines, it is likely to be difficult for businesses to see investment in recycled materials (including purchasing necessary equipment, planning, checking compliance and convincing clients) as worthwhile (ibid).

A lack of uniform standards and reporting frameworks raises serious issues for accountability and CSR across the industry. The issues discussed above are just two examples of this. Without strict reporting requirements or regulations, there remains a risk that CSR will amount to little more than a marketing tactic or a corporate exercise in "white- or green-washing" (Finger & Kilcoyne 1997; Crowther 2002; Barth & Wolff 2009). These views were also supported by interviewees, who expressed concerns that CSR should be measured/monitored and that people should not be able to make claims about CSR without being able to "prove it".

Interviewees also saw the introduction of targeted business incentives as an effective mechanism for improving CSR in the industry. For example one interviewee remarked:

The only way smaller size companies are going to do it is if there was a reward for doing it...If big business and government put in rewards for companies to meet some goals then it can happen.

Interviewees frequently stated that government tenders are now looking to see what businesses are prepared to do in terms of CSR and community engagement. For example, one interviewee stated that if the tender was for a project in an area with a large Indigenous population it would help if the company could demonstrate how the project would help contribute to Indigenous well-being or that the company was committed to improving Indigenous well-being in other

ways. As one interviewee commented, “track record helps” with this process if you are able to demonstrate that you have done this in the past and it is a part of normal business practice rather than just a response to the requirements of the tender. However, at this stage most interviewees argued that this component of government tendering was “not a deal breaker” but was likely to “value-add” to the tender and “give you an edge”.

The Australian Government has also introduced business incentives which indirectly encourage CSR in the industry. For example, the Federal Government established the Australian Government Building and Construction OH&S Accreditation Scheme which is administered by the Office of the Federal Safety Commissioner. The scheme requires that all construction contractors engaged on public sector construction projects have satisfactory levels of OH&S performance and management processes and establishes strict accreditation requirements for all head contractors engaged on government agency contracts (Lingard et al. 2009). While the scheme creates a strong business incentive for the implementation of CSR in relation to OH&S, the dominance of the private sector restricts the impacts of such schemes on the industry as a whole. For example in 2002-2003 the reported income of construction business in Australia was \$140.9 billion, of which only 11 per cent was accounted for by federal state and local government organisation, with the householders and other organisations accounting for 82 per cent of this income (Lingard et al. 2009).

In order for such schemes to have a dramatic impact on CSR performance in the industry, they would need to be extended to the private sector. The increase and introduction of further levies for landfill and subsidies for the use of recycled materials is just one example of how government could introduce business incentives which encourage the improvement of CSR across the industry (Tam 2009). Consumer demand is also likely to play a significant role in determining levels of CSR adoption by companies in the industry. Thus, efforts aimed at cultural change must focus not only on the industry, but also on clients and the general public. For example, evidence suggests that negative perceptions and lack of information regarding reused products from a client’s perspective tend to hinder its use in the construction industry (da Rocha and Sattler 2009). Accordingly, education, training and the provision of accurate information and adequate support structures are key elements in enabling improvements in CSR in the industry.

4.3 Informal Mechanisms to Improve CSR in the Australian Construction Industry

The legislative measures discussed above would clearly be enhanced by initiatives which seek to build on the informal approach to CSR adopted by SMEs and capitalise on the CSR “business cultures” they have already developed. For example, the main drivers to CSR identified by interviewees were proprietor motivation and business culture. These findings support those of the ACCSR (2007) which identified lack of management support as another major obstacle to CSR success. For example, one participant commented that SMEs need someone in their organisation that “has a heart for the community” and that this “has to be genuine or it won’t work”. These findings are supported Jenkins’ (2006) argument about the importance of proprietor motivation in driving CSR. In his study of “Small Business Champions” in the UK, Jenkins (2006: 251) argued that:

In order for CSR to work in a company, it must have an internal champion; top-level management commitment is crucial to its success.

As in Jenkins' study, we found that in all of the companies interviewed, the senior partner or owner-manager were seen as directly responsible for directing CSR principles and "moulding the company culture in their own beliefs" (ibid). For example, one interviewee remarked that the "value system starts at the top" and permeates down the businesses with managers and senior managers "to make sure CSR is part of the culture and the value system." Similarly, interviewees also mentioned the importance of getting 'buy-in' from the employees. One manager stated "I couldn't do it if I didn't have others around me that cared also". Various strategies were discussed to increase employee attachment to CSR, including involving them in CSR decisions and targeting initiatives of immediate interest to employees. Effective CSR strategies should seek to involve and motivate owner-managers and encourage them to integrate CSR into their "business culture" as part of "the way we do business". As argued by Jenkins (2006:253):

SMEs can also exert pressure themselves through the supply chain by championing CSR and encouraging suppliers and customers to adopt socially and environmentally responsible behaviour.

Initiatives to improve CSR performance in the industry also need to take into account the specific barriers and pressures faced by SMEs. Our research found that the major barrier to CSR identified by interviewees was cost in terms of time and money. These findings again support those of the ACCSR (2007) which identified limited financial and human resources as the final major barrier to CSR success. Interview responses confirmed Lingard et al.'s (2009) contention that the focus of SMEs "is often on business survival", and that these smaller companies are unlikely to dedicate the required time and energy into the development of such policies and practices. However, while SMEs are unlikely to have the resources to provide leadership in this area, interviewees frequently acknowledged a willingness to work closely with training and professional bodies to make necessary improvements.

Similarly, there was a clear sense in the interviews that many interviewees saw CSR responsibilities as being more appropriately dealt with by others in the building and construction procurement chain. One participant stated that by the time a building project came down to them, all the important decisions had usually already been made by others involved in the process including: clients, architects, and engineers. As such there was a feeling that the extent to which SMEs and construction companies in general could engage in CSR was "very limited by the other people working on the project." For example, dealing with subcontractors or others involved in the process was the next most commonly identified barrier to CSR identified by interviewees. As one interviewee stated industry structure was a big issue in:

the way that it sort of sub-contracts most things out these days – in the old days I would provide my own labour that I employed – in the old days it would have been a lot easier to control your impact on corporate social responsibility because you have more control over your resources - but these days it all gets watered down – a builder has so few resources on any job these days that he can't guarantee that...

There is a clear role here for professional organisations and training bodies to assist in promoting a more co-ordinated and unified approach to CSR in the industry. The major employer associations and groups in the Australian construction industry include: the Australian Constructors Association (ACA); Master Builders of Australia Inc. (MBA); Civil Contractors Federation (CCF); Housing Industry Association Limited (HIA); and Australian Industry Group

(AIG) (Lingard et al. 2009). Membership varies from large companies to single person providers and across diverse sectors including housing, commercial building and civil engineering projects (ibid). While Lingard et al. (ibid) identified the fragmented nature of the industry, as reflected in the diversity of professional associations, as a barrier to CSR these same factors also mean that professional associations and bodies have a wide reach in the industry. The establishment of an industry wide code of ethics, incorporating CSR principles, which could be promoted through all professional and training organisations in the industry, would go a long way towards addressing many of the issues with CSR, which result from the fragmentation of the industry. Professional organisations and training bodies also play a key networking role which could be leveraged to promote CSR. Through professional bodies companies could share examples of CSR initiatives and policies they have developed, a process which could be encouraged through the hosting of CSR awards nights. Education and training in relation to CSR is a key issue within the industry, as demonstrated by the lack of knowledge in relation to the topic and one interviewee's comments that they had never attended a lecture or seminar on CSR. One participant suggested that CSR should be one of the subjects taught at University as part of the Built Environment degrees and there is definite scope for them to be included in the seminar series' of professional groups and organisations.

It would also be prudent to involve trade unions in the development, monitoring and implementation of such a code. The Australian Council of Trade Unions (ACTU) consists of 46 affiliated unions representing 1.8 million workers (Cole 2003 cited in Lingard et al. 2009). The Construction, Forestry, Mining and Energy Union (CFMEU) is the largest and most active in the construction industry. Others include the Communications, Electrical, Electronic, Energy, Information, Postal, Plumbing and Allied Services Union of Australia (CEPU); the Australian Worker's Union (AWU) and the Australian Manufacturers Workers Union (AMWU). As pointed out by Lingard et al. (2009), unions have historically played a strong role in advancing CSR in the industry. Unions played a key role during the 'green bans' of the 1970s, when construction workers refused to work on constructions sites which involved the demolition of heritage sites for high-rise developments. Areas saved during the 'green bans' include the Rocks, Centennial Park and the Botanic Gardens in Sydney. Unions have already demonstrated their potential to play a major role in contributing to improvement of CSR adoption in the industry by ensuring there is employee "buy-in", and encouraging compliance with legislation as well as the adoption of informal CSR practices.

5 Conclusion and Further Research

This paper has reported on a preliminary research project which explored how CSR was understood by industry leaders in SMEs in the Australian industry. Our results prompted us to suggest that a combination of measures and approaches would be appropriate to encourage the development of CSR in the industry. Despite an obvious preference among interviewees for CSR to remain as a kind of voluntary and informal "business culture", our research suggests that there is a clear role to be played by regulation and legislation in encouraging the improvement of CSR in the industry. Such measures might include the introduction of mandatory reporting mechanisms and standards, an industry-wide code of ethics, and various business incentives, along with other means of soft-regulation. There is also evidence to suggest that there is a need to clarify and simplify existing legislation to improve compliance and further encourage CSR in

the industry. However, our research suggests that such measures would be enhanced by the introduction of more informal initiatives designed to capitalise on the preference for informal CSR practices among SMEs in the industry. Such initiatives might include: improved education around the concept of CSR and a focus on the role of small business champions, along with mechanisms for networking and exchange of information between firms through professional bodies, unions and training organisations.

Further research may assist in determining the best form for such initiatives to take and which are more likely to succeed, as well as enable a more nuanced understanding of how the applicability and effectiveness of such measures is likely to vary across industry sectors and different size businesses. Future studies on CSR in the Australian construction industry could investigate the differences between the Australian states and territories as there are clear differences in legislative approaches and outcomes in terms of CSR. Research should also seek to provide benchmarks to compare CSR practices and performance across the industry. We recommend the development of a model to assist policymakers and contractors make “socially responsible” decisions and enable the monitoring of the implementation of CSR in the industry. We invite scholars who have an interest in CSR in the construction industry to join us in furthering this research agenda and contributing towards a more economically, environmentally and socially sustainable industry.

Abstract:

The residential sector accounts for 25% of Ireland's total energy consumption, of which 60% is used for space heating. As thermal insulation standards increase, building air tightness is playing an increasing role in both building energy performance and indoor environmental quality. This paper reports on the results of air tightness testing carried out on a small number of dwellings. The paper highlights the paucity of dwelling airtightness data for Ireland. The results are compared to past studies and compliance with the existing standards. While the number of houses tested is small they are broadly representative of urban dwellings in Ireland. The study indicates a misconception that newer buildings are more airtight than older buildings. The paper concludes that good design, attention to detail and rigorous controls throughout construction is vital to delivering air-tight dwellings.

Keywords:

airtightness, measurements, standards, workmanship

1 Introduction

Twenty five percent of Ireland's total energy consumption is accounted for by the residential sector, 60% being used for space heating (SEI, 2008). In recent years, improving fabric insulation standards, mechanical efficiencies and a greater understanding of energy use in buildings has augmented the importance of airtightness to building energy performance. Technical Guidance Document Part L (2008) - Conservation of Fuel and Energy (Dwellings) refers to Envelope Air Permeability testing of new dwellings, setting a 'reasonable upper limit for air permeability' of $10\text{m}^3/\text{hr}/\text{m}^2$ at 50Pascals (DEHLG, 2007). This limit is not onerous when compared to standards in other countries, as shown in Table 1 and the increasingly popular PassivHaus standard requiring an n50 of 0.6 air changes per house (ach) (Hodgson and Establishment, 2008). There is

a general awareness of the importance of airtightness and Ireland, but inertia to change has left the concept of air-tight dwellings in the doldrums.

Table 1. Airtightness Standards
(Sourced: Pan, 2010)

	Max air permeability (m ³ /hr/m ² at 50Pa)	Max air change rate (ach at 50 Pa)
Ireland	10	
Netherlands		6
Switzerland		3.6
Germany		1.8 - 3.6
Denmark		2.8
Estonian		3
Finland		1

Internationally, dwelling airtightness characteristics have been well researched (see (Sherman, 1987; Stephen, 2000; Pan, 2010), and in particular in the USA where over 70,000 fan pressurisation measurements have been collected and analysed, comparing air tightness in terms of age, size, and construction type (Chan *et al.*, 2005).

However, there is a paucity of real data relating to the airtightness characteristics of existing dwellings in Ireland. There is a common perception that newer dwelling airtightness is better than for older buildings, however, in Ireland due to the lack of empirical data this cannot be confirmed.

The paper reports on airtightness test results for two sets of houses; 1) 7 single family dwellings completed in early 2008, during Ireland's building boom, 2) 4 single family dwellings constructed in the 1980's; two of the houses have been retrofitted.

2 Dwelling Typology

This study focuses on the quantitative data gathered from 11 occupied single family residential semi-detached houses. All dwellings were of similar construction type; each had two-storeys, three bedrooms and load bearing external cavity walls and was naturally ventilated. Ground floors were slab-on-grade with suspended timber first floors. The attic space was of typical cold roof construction with insulation between ceiling joists. The average floor area and volume of the studied houses was 80m² and 217m³, respectively. Ventilation was provided by passive wall vents designed with closable hit-and-miss or permanently open louvered vent grilles in each room.

2.1 2008 Dwellings

The 2008 dwellings were part of a development of over 60 dwellings. The buildings had brick outer leaf and block inner leaf wall of 100mm cavity wall construction with full fill bonded bead

insulation, 200mm of attic insulation, gas fired central heating and double glazing. Mechanical extractor fans were fitted in bathrooms. The houses typically have a draught lobby to the front and WC to the rear of the building.

2.2 1980's Dwellings

These identical dwellings were part of a large development. The dwellings which had not retrofitting carried out were typical of houses constructed prior to the implementation of minimum insulation standards in Ireland. The buildings had 100mm masonry cavity walls, with no insulation provided at construction, single glazed windows and no central heating. Nominal 100mm fibre attic insulation placed between the joists had degraded over time, providing little insulation value.

The retrofitted dwelling were identical to the as built dwellings but were retrofitted with double glazed windows and doors, 100mm bonded-bead cavity wall insulation, 200mm glass fibre insulation between and across joists in the attic, and gas fired central heating.

3 Test Procedure

In accordance with the requirements of Part L of the building regulations, the air tightness testing was carried out in accordance with the Air Tightness Testing and Measurement Association (ATTMA) Technical Standard, which is based on EN 13829:2000 "Thermal performance of buildings: determination of air permeability of buildings: fan pressurisation method. The test determines the air flow rate required to maintain a pressure differential of 50 Pascal between the inside and outside of the building envelope. External doors and windows were closed, chimneys and flues sealed, trickle vents, smoke vents and all passive ventilation systems closed but not artificially sealed and internal doors open throughout testing.

A Retrotec Q46 Automated Blower-Door was used to carry out the testing. Pressure and flow rate were controlled using a laptop, connected to a DM-2A Automatic Micro-manometer, which controlled the fan. In addition to the DM-2 the test this software continuously logged a number of parameters including fan flow, test pressure and the area measurements. Prior to testing, dwellings were surveyed and the internal envelope area (A_E) and volume (V) accurately calculated. Software presented the air permeability characteristics in two ways:

- 1) Air Leakage Index - measured as the volume of air passing through each square metre of building envelope in one hour ($\text{m}^3/\text{hr}/\text{m}^2$);
- 2) Air Leakage Rate - Air flow rate at a reference envelope pressure difference by the gross internal volume of the dwelling. Unit: air changes per hour (ach)

Both pressurisation and depressurisation were carried out on each house. This takes account for the potential 'value effect' where components may be pushed open during pressurisation and closed down tightly generating a seal during depressurisation. The average of both tests is taken as the air permeability of the house. In addition to the blower-door testing a survey and smoke pencil test was carried out on each dwelling.

4 Test Results

The results of the blower door tests are presented in Table 2. The mean air leakage index of the 2008 dwellings ranged from 6.02 – 13.34 m³/hr/m², with a mean of 10.4m³/hr/m². Figure 1 graphically demonstrates that 5 from 7 exceeded the Part L ‘reasonable upper limit’ of 10m³/hr/m². The average air leakage index for the two retrofitted dwelling was 5.55 m³/hr/m², and 12.53m³/hr/m² for the as built dwellings. This suggests that retrofitting dwellings can reduce air-permeability of dwellings by over 50%. It may be suggested that cavity wall insulation has a two-fold benefit, a) improving thermal properties of the dwelling and b) sealing the array of cracks and penetrations through the masonry building envelope. Comparing all results the 2008 dataset was not as good as expected and does not correlate well with Pan (2010) and Chan *et al.* (2005) who found evidence suggesting that airtightness of newer dwellings has increased compared with older dwellings.

Table 2. Dwelling characteristics and test results

Dwelling	Year of Construction	Retrofit	Envelope Area m ² (A _E)	Internal Volume m ³ (V)	Ave Air Changes @ 50Pa (ACH)	Ave. Air perm @ 50Pa (m ³ /hr/m ²)
A	2008	No	246	224	6.65	6.02
B	2008	No	246	224	9.02	8.60
C	2008	No	246	224	11.58	10.72

G	2008	No	250	221	13.99	13.34
H	1986	Yes	215	205	5.39	5.14
I	1980	Yes	215	205	6.31	5.96
J	1981	No	215	205	11.66	10.64
K	1981	No	215	205	14.9	14.42

Figure 1. Air Leakage rate comparison with Part L 'reasonable upper limit'

Smoke pencil test observations correlated well with previous research (Sherman and Chan, 2003; Jaggs and Scivyer, 2006) uncovering an array of different leakage paths. Typical leakage locations were junctions between floor and wall at 1st floor level, gaps around attic hatch, letterbox, and leakage through and around windows and doors, penetrations in envelope for plumbing and electrical installations such as light switches and sockets, fire alarms and around waste pipes.

In addition to common leakage paths to all dwelling, the following critical leakage pathways were identified in the 2008 dwellings:

- Service ducts concealing the soil vent and waste pipes, located inside the building envelope extending from the ground floor, into the attic space. The duct also concealed the pipes from the toilet and sink in the bathroom. Joints to internal walls were not sealed and thus provided longitudinal leakage pathways into the attic space.
- Windows were not sealed correctly to the window openings and in many cases the draught seal was partly detached from the frame, or completely missing.
- Many of the wall vent covers were not sealed correctly to the walls, thus leakage pathways remain when vent were closed.

This supports Johnston *et al.* (2004) and Kalamees (2007), findings that workmanship and supervision had a large affect on building airtightness. From the results can clearly be deduced that good design, detailing, specification of materials and construction practice are of fundamental importance when constructing new houses.

5 Conclusions

The field study provides a valuable data set of air tightness measurements for 11 new and 1980's single family dwellings. The outcome of the survey that is summarised below highlights the importance of workmanship and construction detailing in order to achieve the air tightness standards set in current Irish Building Regulations. The field measurements indicate that in the case of retrofitted properties there is a direct link between retrofitting and air tightness.

The key findings are summarised as follows:

The air-permeability of the seven dwellings constructed in 2008 was not as good as expected, with five dwellings exceeding the Part L 'reasonable upper limit' of $10\text{ m}^3/\text{hr}/\text{m}^2$ at 50 Pascal. Surveys attributed the high leakage rates poor design and construction of the internal service duct concealing the soil vent and waste pipes. Draft stripping was partially detached from window frames and in some cases was completely missing. Windows were installed such that leakage paths remained between the window frame and external walls.

The results indicate that retrofitting older dwellings can have a significant impact on airtightness. The two retrofitted houses were in excess of 50% more airtight than the two dwellings that had not been altered. The average air leakage index for retrofitted dwellings was $5.55\text{ m}^3/\text{hr}/\text{m}^2$, far below the $10\text{ m}^3/\text{hr}/\text{m}^2$ target.

Comparing the 2008 and 1980's dwellings results show that new dwellings cannot automatically assumed to be more airtight than older dwellings.

Over the past number of years building regulations have improved and best practice documentation produced, however, in practice there is a lack of will amongst building professionals to adopt new practices to improve dwelling airtightness. To overcome this problem designers and builders must be educated about the importance of building airtightness and trained in best practice approaches for both new and existing dwellings. Workmanship must also be closely controlled with airtightness testing undertaken during and post construction. This paper highlights the lack of practical research in airtightness for new and retrofitted dwellings in Ireland. The study should provoke policy makers to enhance the control requirements of on-site workmanship, and designers to be vigilant about the effect particular details can have on airtightness.

Abstract:

Fire safety in buildings can not be underestimated given the grave losses associated with fire incidences. Legislation has been a useful means of ensuring fire safety in buildings, and in England and Wales, the recent introduction of the Regulatory Reform Fire Safety Order (FSO) 2005 has been mentioned to be a positive progression in fire safety standards. However, since its enactment, compliance with the legislation especially among micro and small organisations continues to trail behind expectation. Given that micro and small organisations constitute an enormous proportion of UK organisations and the success of legislation depends on compliance, it is essential to investigate the reasons behind this low compliance. This research thus sought to explore the potential *reasons* for this situation by the use of qualitative interviews conducted with key duty-holders of the legislation: the enforcing authority; responsible persons; and competent persons. The study reveals that low awareness of the FSO in micro and small organisations is at the heart of the low compliance. Also the lack of a recognised formal qualification system for competent persons makes it difficult for responsible persons to appoint competent persons. Beyond this, micro and small organisations prefer to conduct in-house fire risk assessments despite the danger of the lack of understanding of construction materials and technical issues of Fire Safety by responsible persons. This preference is due to the financial burden of engaging a competent person. Furthermore, reduced contact between businesses/building owners and the fire service under the FSO could also be undermining its compliance. Although it can be argued that the FSO is fairly new and as such it requires time to be fully grasped by organisations, the insight provided by this study is useful in the early identification of potentially problematic areas for early redressing.

Keywords:

fire safety, interview, legislation

1 Introduction

With the widely acknowledged catastrophic effects of fire outbreaks in buildings (e.g. loss of lives and property), over the years, it has been found necessary to have measures that would prevent fire outbreaks in buildings and measures that would mitigate their adverse effects. Notably among the measures are fire safety regulations or legislative instruments, and in England and Wales, the recent consolidation of an assortment of previous fire safety legislation into one

regime that is far more accessible has been hailed as a positive stride in fire safety standards (Alalouff, 2006). This recent legislative instrument, known as the Regulatory Reform Fire Safety Order 2005 (FSO 2005), which came into force in England and Wales in 2006 is considered the most significant overhaul of fire safety legislation for seventy years (Alalouff, 2006).

The FSO 2005 radicalised the fire safety legislation by removing the fire certificate scheme, which was introduced under its repealed predecessor, the Fire Precautions Act 1971. The Reform removed the system of fire certification by the Fire Service, and introduced the notion of self certification or a self regulated assessment system to be conducted by building owners or employers themselves. Under the FSO 2005, owners or managers of any non domestic premises in England and Wales are therefore mandated to undertake, review and update a suitable and sufficient fire risk assessment and take proactive steps to ensure the safety of those on or in the vicinity of the property.

Three years after its coming into force a government review of the FSO 2005 indicates that compliance of the FSO 2005 among micro and small businesses continues to trail behind expectation (see Communities and Local Government, 2009). Micro and small businesses play a key role in the UK economy implying that the success of the FSO 2005 will greatly require their input. This study thus sought to investigate the factors responsible for the trailing compliance of the FSO 2005 among micro and small businesses. In the sections that follow, a review of fire safety legislation in the UK is presented to set the premise for the investigation. This is followed by the research methodology adopted for the study. Subsequently, the findings are presented and discussed followed by concluding remarks.

2 Literature Review: Fire Safety Legislation

The very first indications of UK fire safety standards can be traced back as early as the 12th Century when the Mayor of London laid restrictions on construction materials to prevent the rapid spread of fire through the city. The first tangible piece of enacted legislation, however, was the Fire Prevention (Metropolis) Act 1774. The Act classified building types and stipulated minimum standards in respect to thickness of external and party walls. Importantly, the Act also placed requirements on building owners to provide adequate means of escape; a principle still at the forefront of fire safety standards today (FireNet International, 2009). The 19th Century witnessed a number of further legislative developments for specific building types. The series of new Acts reflected Central Government's understanding that different properties and the activities that were conducted within them carried unique fire safety considerations and that these should be covered by individual Acts rather than generic regulations. During the 19th Century, the Government introduced sector specific regulations including the Theatres Act 1843 and the Factory and Workshop Act 1885 (amended 1891).

Positively, the Government's commitment to improving fire safety standards in workplaces and public buildings gained significant momentum through the 20th Century with a key progression being the enactment of the Fire Precautions Act 1971; the fundamental aspect of which was the fire certificate system. As required by the Fire Precautions Act 1971, the Fire Service would conduct periodic inspections of premises providing a service, and subject to compliance, the premises would receive a fire certificate. Cox (2008) supports the Fire Precautions Act 1971 stating that fire certificates were an effective way in achieving compliance as the responsibility

lay with experienced fire service personnel who can be considered experts in the field. At the close of the century, the Government passed the Fire Precautions (Workplace) Regulations 1997 (as amended 1999) which placed additional obligations on employers. The requirement for the fire certificate remained under the new Act, but above and beyond this, employers had additional legal duty including: conducting a suitable and sufficient fire risk assessment which is monitored, reviewed and revised as appropriate; informing staff of any known risks; making staff aware of an emergency plan; and providing mandatory training to new employees as well as periodic training for existing employees.

Fire safety legislation through the centuries naturally developed in a fragmented fashion; primarily as the result of serious fires or recognised “near misses” (Edwards, 2006). The natural result of such progression was a cacophony of policies, statutory requirements and guidance dispersed across multiple Acts and Regulations which obviously had compliance implications. Again the fire certification introduced by the Fire Precautions Act 1971 and retained under the Fire Precautions (Workplace) Regulations 1997 received criticism. For instance, Hill and Webster (2006) explained that the process of applying for a fire certificate could take up to two years, potentially leaving a property at risk. In addition, Baker (2009) admits that although the certificate was a useful point of reference, building owners and employers often hid behind it and conducted no proactive monitoring or reviewing once it had been awarded. Whilst the fire certificate recorded building compliance, it was therefore only a snapshot in time and did not take into account how the property was being used on a day to day basis.

In 2006, the above criticisms of the fire legislative regime yielded the advent of the FSO 2005 which consolidated the previous fire safety legislation into one regime and also removed the fire certification scheme. The FSO 2005 introduced three key elements: the responsible person; the enforcing body; and the competent person. Under the FSO 2005, the “responsible person” is the person responsible for ensuring fire safety standards are met and this is the employer or a person that is in control of the premises i.e. building owner, occupier or landlord. The responsible person is required to undertake a self certification process through periodic risk assessments (including the frequent monitoring and reviewing of such) as well as comprehensive record keeping. The Fire and Rescue Service fulfils the role of the “enforcing body” and they are required to undertake periodic inspections of premises governed by the FSO 2005 to ensure that responsible persons are fulfilling their duty. By removing the previous fire certificate system, the Order has passed the full responsibility, and ultimate accountability, on to the responsible person and the Fire and Rescue Service are now responsible for visiting sites to ensure that the Order is being observed. The Fire and Rescue Service have the power to: issue an enforcement notice whereby the Fire and Rescue Service clearly stipulates the breaches and a timeframe for rectifying them; issue a prohibition notice to restrict/prevent use of the property until the necessary improvements have been undertaken; and to bring prosecutions in the criminal courts.

Under the FSO 2005, where a property is particularly complex in terms of construction or hazardous in terms of use; or where the responsible person has limited fire safety experience and/or knowledge, it shall be necessary for the responsible person to appoint a third party consultant to assist with the fire risk assessment. This third party is the “competent person”, having sufficient training and experience or knowledge and other qualities to enable him to conduct a suitable and sufficient assessment of the premises. The introduction of the FSO 2005 was however not accompanied by the provision of a Government register of accredited fire risk

assessors, a situation which could result in inadequate consultancies producing substandard assessments which would ultimately leave the responsible person liable. Under the previous legislation, the competent person was effectively the Fire and Rescue Service.

In spite of the FSO 2005 being hailed for the changes it has introduced to fire safety (cf. Alalouff, 2006; and Communities and Local Government, 2009), a report by Communities and Local Government (2009) indicates low compliance among micro and small organisations, and implicates low awareness of the FSO 2005 among micro and small organisations as being responsible. Undoubtedly, this finding is important to efforts geared towards entrenching the impact of the reform. However, beyond the issue of low awareness there could be other undermining factors or challenges drawing back compliance of the FSO among micro and small businesses. Micro and small businesses play a key role in the UK economy accounting for about 99% of UK private businesses and 48% of UK private sector employment (cf. Department for Business Innovation and Skills, 2009). Clearly the success of the FSO 2005 thus requires their input. It is therefore imperative to explore further any challenges that could be undermining compliance of the Reform among micro and small businesses. Indeed doing this will provide further opportunity for the early identification of problematic areas for early redressing. With this background, this study sought to investigate potential issues responsible for the trailing compliance of the FSO 2005 among micro and small businesses with the key research question being: *why* is there low compliance of the FSO among micro and small businesses. To answer the posed research question, the following methodology was adopted.

3 Research Methodology

This research had an exploratory and interpretive focus as it sought to investigate the “*why*” surrounding a phenomenon which in this case is the low compliance of the FSO among micro and small businesses. Such a focus favours the use of a qualitative inquiry as qualitative inquiries are suitable for obtaining meaning and as such are appropriate for answering questions relating to “*why*” and “*how*” (cf. Fellows and Lui, 2008). In view of this, qualitative interviews (in the form of semi-structured interviews) were conducted with the three key duty-holders under the FSO: responsible person, competent person and enforcing body.

As there are no organised records/database of particularly responsible persons and competent persons, purposive sampling was used to obtain participants constituting the three target groups. All the participant’s organisation were based in the West Midland Region of the UK. For both the responsible persons and competent persons categories, 4 participants each were interviewed and one participant for the enforcing body category. In total 9 participants were therefore interviewed. The interviewees were asked a series of questions relating to the significance of the FSO to fire safety, and also challenges in complying with the FSO among micro and small businesses.

The interviews were audio-taped. For the analysis of the interviews, the recorded interviews were transcribed. The transcripts were analysed systematically through iterative re-reading and coding of the transcripts which enabled the attainment of a profound understanding of each interviewee’s view point and hence the extraction of issues relating to the low compliance of the FSO among micro and small businesses (cf. Choudhry and Fang, 2008; Creswell, 2009).

4 Findings and Discussion

Table 1 provides a brief profile of the participants showing their role and experience. Taken together, the Table shows that the participants were in a good position to provide remarks that would yield an understanding of the subject being investigated.

5 Significance of the FSO

There was a general acknowledgement by the participants that the introduction of the FSO was a useful stride in fire safety standards. A theme, which was consistent in all interviews was that the previous legislation invited businesses to rely heavily on their fire certificates. The fire certificate was essentially only a snap shot in time and often businesses did not see any further need for proactive monitoring or undertaking their own regular risk assessments. This was even confirmed by the interviewed responsible persons as none of them had undertaken a fire risk assessment of their premises before the overhaul of the legislation.

“It [fire certificate] was a tick in the audit box, stored in a file and fire safety was given no further thought.” - C4

“[Previously] They’ve [Businesses] got a bit of paper [fire certificate] saying that the property is safe but there was no proactive approach which is what this [Fire Safety Order] is designed to do.”- C3

A further point highlighted by the participants was that the overhaul was necessary as it brought together a great deal of previous “fragmented” legislation, creating one single point of reference. As indicated by the Communities and Local Government (2006), in a bid to reduce death, injury and damage caused by fire, it intended to make the law easier to follow and to comply with. The general consensus revealed by this study is that the FSO has been effective in doing this.

Table 1: Profile of Participants

Enforcing Body Representative		
Participant	Role/Position	Experience
E1	Representative of Enforcing Body	35 years working for the Fire Service and now as an assessor at a Local Authority. Retains contacts and relationship with the Fire Service.
Competent Persons		
Participant	Role/Position	Experience
C1	Chartered Building Surveyor	5 years on a wide range of properties, types and sizes.
C2	CDM Coordinator	5 years small, low risk premises only
C3	Graduate Building Surveyor	3 Years on small/medium sized properties of low/medium risk.
C4	Graduate Building Surveyor	4 years on small/medium sized properties of low/medium risks.
Responsible Persons		
Participant	Type of Organisation & Size	Role/Position
R1	Doctors Surgery *Small organisation	Reception Manager
R2	Public House *Small organisation	Owner
R3	Rugby Club *Micro organisation	Chairman of the Recreational Trust
R4	Electrical Contracting Firm * Small organisation	Managing Director and also Landlord of multi-occupied premises

* Micro organisation has ≤ 9 employees. Small enterprise has ≤ 49 employees

Another view shared by most of the respondents was that by creating the role of responsible persons, and ultimately a single point of accountability, people were encouraged to pay more attention to the legislation. One participant explained that the fear of prosecution prompts him to take the role seriously.

“As I said, I think it crystallises exactly how you should be doing things. And because you know there is a burden of responsibility on everyone I think it makes you more aware. It does make you more aware.” - R1

“I think it scares people. We live in a blame/claim culture and I think that the legislation has created that one point of blame in the responsible person. In a way, I hope it scares people into fulfilling their obligations. I know it would have that effect on me if I was in that position.” - C4

“I am the owner and I always feel the buck stops at me. It is a burden but a burden that comes with being your own boss and being responsible for staff and customers.” - R2

Overall, regarding the significance of the FSO this study like the Communities and Local Government (2009) report indicates that introducing the FSO was a useful overhaul of fire

legislation. However, despite this view, one participant (i.e. E1) viewed the Fire Precautions Act 1971 as having performed an effective role in raising fire safety standards and that the FSO is essentially about maintaining those high standards as opposed to vastly improving them.

6 Challenges with compliance of FSO among micro and small businesses

As identified from the interviews, the issues undermining compliance of the FSO among micro and small businesses are as illustrated in Figure 1.

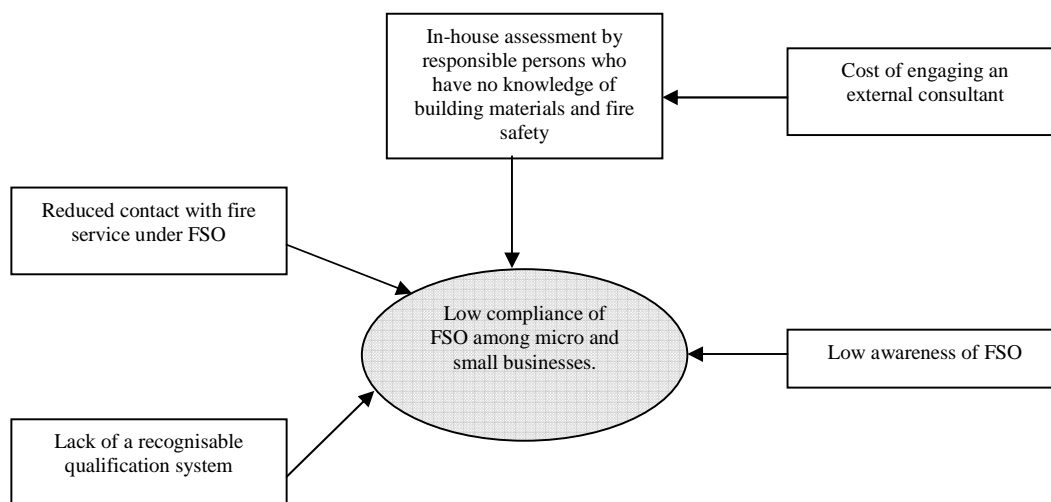

Figure 1: Issues undermining compliance of FSO among micro and small businesses

6.1 Low awareness

Although all the interviewed responsible persons are aware of the FSO, the participants were of the view that there is low awareness of the FSO among micro and small organisations, particularly in terms of full understanding of their legal duties and the implications of non-compliance. This finding thus corroborates the Local Government (2009) report which similarly identified low awareness of the FSO among micro and small organisations as being behind the trailing compliance of the FSO among micro and small organisations. Comments by the interviewed competent persons and enforcing body representative pointed to inadequate government publicity of the FSO.

“I don’t think it [FSO] has been well communicated. I have not seen any adverts, TV or radio. That’s not to say that is hasn’t been advertised but I haven’t seen it. I am only aware of it because of the line of work I’m in: working in construction.” - C1

Authors are not advised to use more than three levels of subsections’ nesting. The use of too many nesting levels will reduce clarity and may be confusing for the readers of the article.

6.2 Lack of background knowledge of building materials and fire safety by responsible persons

A common view held by the interviewed competent persons was that majority of micro and small organisations are conducting in-house fire risk assessment and that often the responsible

persons assessing their own premises do not have the background knowledge of construction materials and the technical issues of fire safety and thus potentially leading to substandard assessments. The financial burden of consultancy fees was mentioned as being the reason for many micro and small businesses not using competent persons/consultants.

Although the competent persons acknowledged the government guidance documents on the FSO as being useful, they considered it as not being absolute and having several grey areas which may prove difficult for a lay person to make a good judgement if they are not experienced in undertaking assessments. However, contrary to the views of the interviewed competent persons, three of the responsible persons felt that with the assistance of the government guidance documents, they were competent enough to complete the fire risk assessment themselves. Not surprising, these three responsible persons indicated that they had conducted the risk assessment themselves instead of appointing a third party consultant.

“.....they [responsible persons] might be using the guidance document for the theoretical approach but do not have good background knowledge of building material i.e. compartments, fire resisting construction or perhaps material that would aid the rapid spread of fire.” – C4

6.3 Lack of a recognised formal qualification system for competent persons.

The introduction of the FSO was not accompanied by a formal qualification system for competent persons and this lack was identified as making appointment of competent persons difficult for responsible persons as responsible persons can not be certain that the competent persons they appoint have sufficient training, experience and knowledge of fire risk assessment. This has consequences for compliance of the FSO (not just for micro and small organisations but also for larger organisations) as there could be substandard assessment for organisations who choose to appoint external assessors. A common view held by the participants was thus the need for the establishment of an independent recognisable qualification for all assessors and an amendment of the FSO to stipulate the qualification as a legal requirement.

“Good fire safety practices can mean the difference between life and death so it is pretty essential that the people assessing those practices are competent to do it. And how do you know they are unless they have been formally assessed by an independent body? I also think it would help responsible persons select an assessor. I wouldn’t be surprised if responsible persons are getting sub standards assessments without knowing it.” – C4

6.4 Reduced contact with the Fire Service.

Some of the participants, opined that contact between the fire service and micro and small organisations will be reduced under the FSO as the fire service will be unable to inspect all properties. Two out of four interviewed responsible persons had received a visit from the fire Service since the introduction of the FSO. It was expressed that reducing the fire service’s contact with micro and small organisation was dangerous and could lower fire safety standards.

7 Conclusions and Recommendations

Despite the general acceptance of the FSO as a useful stride in fire safety, its compliance among micro and small businesses has been a challenge as compliance among this category trails behind expectation. Contributing to earlier studies on the FSO, this study has buttressed earlier findings

and also yielded further insight into the low compliance of the FSO among micro and small businesses. These have implications for the success of the FSO and as such early consideration should be given to formulating policies and devising measures to address the reasons for the low compliance.

Concerning the issue of awareness, further publicity efforts targeting micro and small organisations at the local level (e.g. councils) would be useful. The publicity could take the form of open days or seminars at local fire service stations. The publicity could also take the form of periodic newsletters (advisably electronic to minimise cost) sent by local fire services to businesses within their locality. In order to assist responsible persons who wish to undertake in-house assessment, these seminars could be made to compliment government guidance documents by also serving the purpose of providing responsible persons with some rudimentary knowledge of building materials and fire risk assessments. The e-newsletters could also be a useful means by which local fire services could disseminate information on recent fires within the locality, the exact causes and advice on preventing similar incidents.

Regarding the lack of a government recognised certification scheme for competent persons, it will be useful if such a mandatory scheme is provided. However, this should be preceded by stakeholder discussions to delineate the operational details of the scheme. Obviously, given the large number of micro and small businesses it will be difficult for the fire services to visit all micro and small businesses. However, the inspection of such businesses, particularly those with premises of high risk could be given greater priority. More importantly micro and small businesses should be encouraged to contact their local fire services for any assistance and advice they may need in complying with their legal obligation under the FSO.

Admittedly, the FSO is fairly new and may take some while to be fully grasped by micro and small organisations. This however does not remove the need to take early steps to enable the entrenchment of the benefits of FSO. There still remains room for improvement and it is hoped that the findings of this inquiry and the recommendations together with previous reports on the FSO would be useful in contributing to safer premises amongst micro and small organisations.

1 Introduction

With the widely acknowledged catastrophic effects of fire outbreaks in buildings (e.g. loss of lives and property), over the years, it has been found necessary to have measures that would prevent fire outbreaks in buildings and measures that would mitigate their adverse effects. Notably among the measures are fire safety regulations or legislative instruments, and in England and Wales, the recent consolidation of an assortment of previous fire safety legislation into one

regime that is far more accessible has been hailed as a positive stride in fire safety standards (Alalouff, 2006). This recent legislative instrument, known as the Regulatory Reform Fire Safety Order 2005 (FSO 2005), which came into force in England and Wales in 2006 is considered the most significant overhaul of fire safety legislation for seventy years (Alalouff, 2006).

The FSO 2005 radicalised the fire safety legislation by removing the fire certificate scheme, which was introduced under its repealed predecessor, the Fire Precautions Act 1971. The Reform removed the system of fire certification by the Fire Service, and introduced the notion of self certification or a self regulated assessment system to be conducted by building owners or employers themselves. Under the FSO 2005, owners or managers of any non domestic premises in England and Wales are therefore mandated to undertake, review and update a suitable and sufficient fire risk assessment and take proactive steps to ensure the safety of those on or in the vicinity of the property.

Three years after its coming into force a government review of the FSO 2005 indicates that compliance of the FSO 2005 among micro and small businesses continues to trail behind expectation (see Communities and Local Government, 2009). Micro and small businesses play a key role in the UK economy implying that the success of the FSO 2005 will greatly require their input. This study thus sought to investigate the factors responsible for the trailing compliance of the FSO 2005 among micro and small businesses. In the sections that follow, a review of fire safety legislation in the UK is presented to set the premise for the investigation. This is followed by the research methodology adopted for the study. Subsequently, the findings are presented and discussed followed by concluding remarks.

2 Literature Review: Fire Safety Legislation

The very first indications of UK fire safety standards can be traced back as early as the 12th Century when the Mayor of London laid restrictions on construction materials to prevent the rapid spread of fire through the city. The first tangible piece of enacted legislation, however, was the Fire Prevention (Metropolis) Act 1774. The Act classified building types and stipulated minimum standards in respect to thickness of external and party walls. Importantly, the Act also placed requirements on building owners to provide adequate means of escape; a principle still at the forefront of fire safety standards today (FireNet International, 2009). The 19th Century witnessed a number of further legislative developments for specific building types. The series of new Acts reflected Central Government's understanding that different properties and the activities that were conducted within them carried unique fire safety considerations and that these should be covered by individual Acts rather than generic regulations. During the 19th Century, the Government introduced sector specific regulations including the Theatres Act 1843 and the Factory and Workshop Act 1885 (amended 1891).

Positively, the Government's commitment to improving fire safety standards in workplaces and public buildings gained significant momentum through the 20th Century with a key progression being the enactment of the Fire Precautions Act 1971; the fundamental aspect of which was the fire certificate system. As required by the Fire Precautions Act 1971, the Fire Service would conduct periodic inspections of premises providing a service, and subject to compliance, the premises would receive a fire certificate. Cox (2008) supports the Fire Precautions Act 1971 stating that fire certificates were an effective way in achieving compliance as the responsibility

lay with experienced fire service personnel who can be considered experts in the field. At the close of the century, the Government passed the Fire Precautions (Workplace) Regulations 1997 (as amended 1999) which placed additional obligations on employers. The requirement for the fire certificate remained under the new Act, but above and beyond this, employers had additional legal duty including: conducting a suitable and sufficient fire risk assessment which is monitored, reviewed and revised as appropriate; informing staff of any known risks; making staff aware of an emergency plan; and providing mandatory training to new employees as well as periodic training for existing employees.

Fire safety legislation through the centuries naturally developed in a fragmented fashion; primarily as the result of serious fires or recognised “near misses” (Edwards, 2006). The natural result of such progression was a cacophony of policies, statutory requirements and guidance dispersed across multiple Acts and Regulations which obviously had compliance implications. Again the fire certification introduced by the Fire Precautions Act 1971 and retained under the Fire Precautions (Workplace) Regulations 1997 received criticism. For instance, Hill and Webster (2006) explained that the process of applying for a fire certificate could take up to two years, potentially leaving a property at risk. In addition, Baker (2009) admits that although the certificate was a useful point of reference, building owners and employers often hid behind it and conducted no proactive monitoring or reviewing once it had been awarded. Whilst the fire certificate recorded building compliance, it was therefore only a snapshot in time and did not take into account how the property was being used on a day to day basis.

In 2006, the above criticisms of the fire legislative regime yielded the advent of the FSO 2005 which consolidated the previous fire safety legislation into one regime and also removed the fire certification scheme. The FSO 2005 introduced three key elements: the responsible person; the enforcing body; and the competent person. Under the FSO 2005, the “responsible person” is the person responsible for ensuring fire safety standards are met and this is the employer or a person that is in control of the premises i.e. building owner, occupier or landlord. The responsible person is required to undertake a self certification process through periodic risk assessments (including the frequent monitoring and reviewing of such) as well as comprehensive record keeping. The Fire and Rescue Service fulfils the role of the “enforcing body” and they are required to undertake periodic inspections of premises governed by the FSO 2005 to ensure that responsible persons are fulfilling their duty. By removing the previous fire certificate system, the Order has passed the full responsibility, and ultimate accountability, on to the responsible person and the Fire and Rescue Service are now responsible for visiting sites to ensure that the Order is being observed. The Fire and Rescue Service have the power to: issue an enforcement notice whereby the Fire and Rescue Service clearly stipulates the breaches and a timeframe for rectifying them; issue a prohibition notice to restrict/prevent use of the property until the necessary improvements have been undertaken; and to bring prosecutions in the criminal courts.

Under the FSO 2005, where a property is particularly complex in terms of construction or hazardous in terms of use; or where the responsible person has limited fire safety experience and/or knowledge, it shall be necessary for the responsible person to appoint a third party consultant to assist with the fire risk assessment. This third party is the “competent person”, having sufficient training and experience or knowledge and other qualities to enable him to conduct a suitable and sufficient assessment of the premises. The introduction of the FSO 2005 was however not accompanied by the provision of a Government register of accredited fire risk

assessors, a situation which could result in inadequate consultancies producing substandard assessments which would ultimately leave the responsible person liable. Under the previous legislation, the competent person was effectively the Fire and Rescue Service.

In spite of the FSO 2005 being hailed for the changes it has introduced to fire safety (cf. Alalouff, 2006; and Communities and Local Government, 2009), a report by Communities and Local Government (2009) indicates low compliance among micro and small organisations, and implicates low awareness of the FSO 2005 among micro and small organisations as being responsible. Undoubtedly, this finding is important to efforts geared towards entrenching the impact of the reform. However, beyond the issue of low awareness there could be other undermining factors or challenges drawing back compliance of the FSO among micro and small businesses. Micro and small businesses play a key role in the UK economy accounting for about 99% of UK private businesses and 48% of UK private sector employment (cf. Department for Business Innovation and Skills, 2009). Clearly the success of the FSO 2005 thus requires their input. It is therefore imperative to explore further any challenges that could be undermining compliance of the Reform among micro and small businesses. Indeed doing this will provide further opportunity for the early identification of problematic areas for early redressing. With this background, this study sought to investigate potential issues responsible for the trailing compliance of the FSO 2005 among micro and small businesses with the key research question being: *why* is there low compliance of the FSO among micro and small businesses. To answer the posed research question, the following methodology was adopted.

3 Research Methodology

This research had an exploratory and interpretive focus as it sought to investigate the “*why*” surrounding a phenomenon which in this case is the low compliance of the FSO among micro and small businesses. Such a focus favours the use of a qualitative inquiry as qualitative inquiries are suitable for obtaining meaning and as such are appropriate for answering questions relating to “*why*” and “*how*” (cf. Fellows and Lui, 2008). In view of this, qualitative interviews (in the form of semi-structured interviews) were conducted with the three key duty-holders under the FSO: responsible person, competent person and enforcing body.

As there are no organised records/database of particularly responsible persons and competent persons, purposive sampling was used to obtain participants constituting the three target groups. All the participant’s organisation were based in the West Midland Region of the UK. For both the responsible persons and competent persons categories, 4 participants each were interviewed and one participant for the enforcing body category. In total 9 participants were therefore interviewed. The interviewees were asked a series of questions relating to the significance of the FSO to fire safety, and also challenges in complying with the FSO among micro and small businesses.

The interviews were audio-taped. For the analysis of the interviews, the recorded interviews were transcribed. The transcripts were analysed systematically through iterative re-reading and coding of the transcripts which enabled the attainment of a profound understanding of each interviewee’s view point and hence the extraction of issues relating to the low compliance of the FSO among micro and small businesses (cf. Choudhry and Fang, 2008; Creswell, 2009).

4 Findings and Discussion

Table 1 provides a brief profile of the participants showing their role and experience. Taken together, the Table shows that the participants were in a good position to provide remarks that would yield an understanding of the subject being investigated.

4.1 Significance of the FSO

There was a general acknowledgement by the participants that the introduction of the FSO was a useful stride in fire safety standards. A theme, which was consistent in all interviews was that the previous legislation invited businesses to rely heavily on their fire certificates. The fire certificate was essentially only a snap shot in time and often businesses did not see any further need for proactive monitoring or undertaking their own regular risk assessments. This was even confirmed by the interviewed responsible persons as none of them had undertaken a fire risk assessment of their premises before the overhaul of the legislation.

“It [fire certificate] was a tick in the audit box, stored in a file and fire safety was given no further thought.” - C4

“[Previously] They’ve [Businesses] got a bit of paper [fire certificate] saying that the property is safe but there was no proactive approach which is what this [Fire Safety Order] is designed to do.” - C3

A further point highlighted by the participants was that the overhaul was necessary as it brought together a great deal of previous “fragmented” legislation, creating one single point of reference. As indicated by the Communities and Local Government (2006), in a bid to reduce death, injury and damage caused by fire, it intended to make the law easier to follow and to comply with. The general consensus revealed by this study is that the FSO has been effective in doing this.

Table 1: Profile of Participants

Enforcing Body Representative		
Participant	Role/Position	Experience
E1	Representative of Enforcing Body	35 years working for the Fire Service and now as an assessor at a Local Authority. Retains contacts and relationship with the Fire Service.
Competent Persons		
Participant	Role/Position	Experience
C1	Chartered Building Surveyor	5 years on a wide range of properties, types and sizes.
C2	CDM Coordinator	5 years small, low risk premises only
C3	Graduate Building Surveyor	3 Years on small/medium sized properties of low/medium risk.
C4	Graduate Building Surveyor	4 years on small/medium sized properties of low/medium risks.
Responsible Persons		
Participant	Type of Organisation & Size	Role/Position
R1	Doctors Surgery *Small organisation	Reception Manager
R2	Public House *Small organisation	Owner
R3	Rugby Club *Micro organisation	Chairman of the Recreational Trust
R4	Electrical Contracting Firm * Small organisation	Managing Director and also Landlord of multi-occupied premises

* Micro organisation has ≤ 9 employees. Small enterprise has ≤ 49 employees

Another view shared by most of the respondents was that by creating the role of responsible persons, and ultimately a single point of accountability, people were encouraged to pay more attention to the legislation. One participant explained that the fear of prosecution prompts him to take the role seriously.

“As I said, I think it crystallises exactly how you should be doing things. And because you know there is a burden of responsibility on everyone I think it makes you more aware. It does make you more aware.” - R1

“I think it scares people. We live in a blame/claim culture and I think that the legislation has created that one point of blame in the responsible person. In a way, I hope it scares people into fulfilling their obligations. I know it would have that effect on me if I was in that position.” - C4

“I am the owner and I always feel the buck stops at me. It is a burden but a burden that comes with being your own boss and being responsible for staff and customers.” - R2

Overall, regarding the significance of the FSO this study like the Communities and Local Government (2009) report indicates that introducing the FSO was a useful overhaul of fire

legislation. However, despite this view, one participant (i.e. E1) viewed the Fire Precautions Act 1971 as having performed an effective role in raising fire safety standards and that the FSO is essentially about maintaining those high standards as opposed to vastly improving them.

4.2 Challenges with compliance of FSO among micro and small businesses

As identified from the interviews, the issues undermining compliance of the FSO among micro and small businesses are as illustrated in Figure 1.

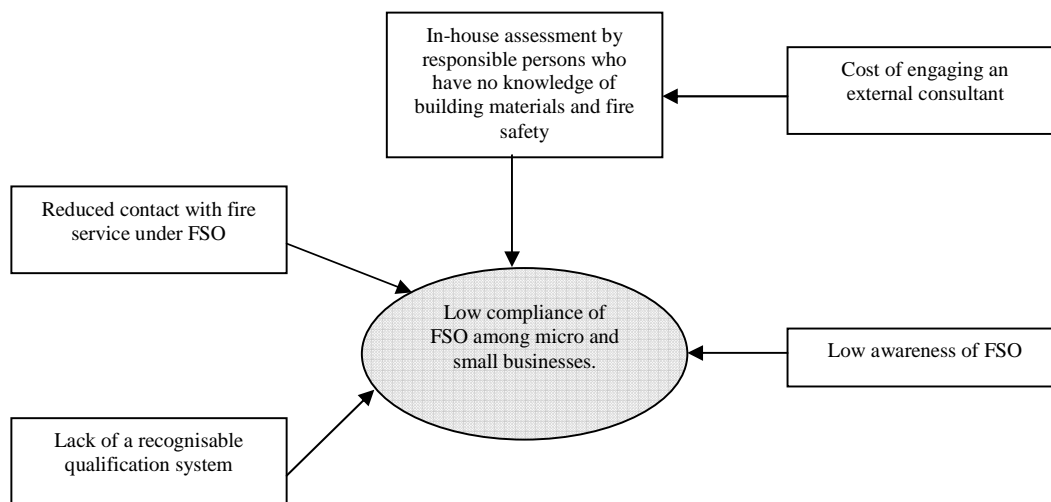

Figure 1: Issues undermining compliance of FSO among micro and small businesses

4.2.1 Low awareness

Although all the interviewed responsible persons are aware of the FSO, the participants were of the view that there is low awareness of the FSO among micro and small organisations, particularly in terms of full understanding of their legal duties and the implications of non-compliance. This finding thus corroborates the Local Government (2009) report which similarly identified low awareness of the FSO among micro and small organisations as being behind the trailing compliance of the FSO among micro and small organisations. Comments by the interviewed competent persons and enforcing body representative pointed to inadequate government publicity of the FSO.

“I don’t think it [FSO] has been well communicated. I have not seen any adverts, TV or radio. That’s not to say that is hasn’t been advertised but I haven’t seen it. I am only aware of it because of the line of work I’m in: working in construction.”- C1

Authors are not advised to use more than three levels of subsections’ nesting. The use of too many nesting levels will reduce clarity and may be confusing for the readers of the article.

4.2.2 Lack of background knowledge of building materials and fire safety by responsible persons

A common view held by the interviewed competent persons was that majority of micro and small organisations are conducting in-house fire risk assessment and that often the responsible persons assessing their own premises do not have the background knowledge of construction

materials and the technical issues of fire safety and thus potentially leading to substandard assessments. The financial burden of consultancy fees was mentioned as being the reason for many micro and small businesses not using competent persons/consultants.

Although the competent persons acknowledged the government guidance documents on the FSO as being useful, they considered it as not being absolute and having several grey areas which may prove difficult for a lay person to make a good judgement if they are not experienced in undertaking assessments. However, contrary to the views of the interviewed competent persons, three of the responsible persons felt that with the assistance of the government guidance documents, they were competent enough to complete the fire risk assessment themselves. Not surprising, these three responsible persons indicated that they had conducted the risk assessment themselves instead of appointing a third party consultant.

“.....they [responsible persons] might be using the guidance document for the theoretical approach but do not have good background knowledge of building material i.e. compartments, fire resisting construction or perhaps material that would aid the rapid spread of fire.” – C4

4.2.3 Lack of a recognised formal qualification system for competent persons.

The introduction of the FSO was not accompanied by a formal qualification system for competent persons and this lack was identified as making appointment of competent persons difficult for responsible persons as responsible persons can not be certain that the competent persons they appoint have sufficient training, experience and knowledge of fire risk assessment. This has consequences for compliance of the FSO (not just for micro and small organisations but also for larger organisations) as there could be substandard assessment for organisations who choose to appoint external assessors. A common view held by the participants was thus the need for the establishment of an independent recognisable qualification for all assessors and an amendment of the FSO to stipulate the qualification as a legal requirement.

“Good fire safety practices can mean the difference between life and death so it is pretty essential that the people assessing those practices are competent to do it. And how do you know they are unless they have been formally assessed by an independent body? I also think it would help responsible persons select an assessor. I wouldn’t be surprised if responsible persons are getting sub standards assessments without knowing it.” – C4

4.2.4 Reduced contact with the Fire Service.

Some of the participants, opined that contact between the fire service and micro and small organisations will be reduced under the FSO as the fire service will be unable to inspect all properties. Two out of four interviewed responsible persons had received a visit from the fire Service since the introduction of the FSO. It was expressed that reducing the fire service’s contact with micro and small organisation was dangerous and could lower fire safety standards.

5 Conclusions and Recommendations

Despite the general acceptance of the FSO as a useful stride in fire safety, its compliance among micro and small businesses has been a challenge as compliance among this category trails behind expectation. Contributing to earlier studies on the FSO, this study has buttressed earlier findings and also yielded further insight into the low compliance of the FSO among micro and small

businesses. These have implications for the success of the FSO and as such early consideration should be given to formulating policies and devising measures to address the reasons for the low compliance.

Concerning the issue of awareness, further publicity efforts targeting micro and small organisations at the local level (e.g. councils) would be useful. The publicity could take the form of open days or seminars at local fire service stations. The publicity could also take the form of periodic newsletters (advisably electronic to minimise cost) sent by local fire services to businesses within their locality. In order to assist responsible persons who wish to undertake in-house assessment, these seminars could be made to compliment government guidance documents by also serving the purpose of providing responsible persons with some rudimentary knowledge of building materials and fire risk assessments. The e-newsletters could also be a useful means by which local fire services could disseminate information on recent fires within the locality, the exact causes and advice on preventing similar incidents.

Regarding the lack of a government recognised certification scheme for competent persons, it will be useful if such a mandatory scheme is provided. However, this should be preceded by stakeholder discussions to delineate the operational details of the scheme. Obviously, given the large number of micro and small businesses it will be difficult for the fire services to visit all micro and small businesses. However, the inspection of such businesses, particularly those with premises of high risk could be given greater priority. More importantly micro and small businesses should be encouraged to contact their local fire services for any assistance and advice they may need in complying with their legal obligation under the FSO.

Admittedly, the FSO is fairly new and may take some while to be fully grasped by micro and small organisations. This however does not remove the need to take early steps to enable the entrenchment of the benefits of FSO. There still remains room for improvement and it is hoped that the findings of this inquiry and the recommendations together with previous reports on the FSO would be useful in contributing to safer premises amongst micro and small organisations.

Building technology

Using an Analytics Engine to Understand the Design and Construction of Domestic Buildings

Sidney Newton and Russell Lowe

Faculty of Built Environment,
The University of New South Wales, Sydney, 2052,
Australia

Email: s.newton@unsw.edu.au; russell.lowe@unsw.edu.au

Abstract:

Understanding domestic building technology is fundamental to the learning and teaching of building and construction. Like any subject dealing with technology and process, domestic construction makes most sense when it can directly be experienced by the learner. One possibility is to develop the rich visual and behavioural modelling capabilities of advanced video game engines such as Crytek CryENGINE®2. This game engine has been modified to perform as an analytics engine specific to the design and construction of domestic buildings. The system is currently being developed and trialled as a learning and teaching resource with a large cohort of undergraduate construction management students. Users are required to source a variety of tools within the game environment which they use to analyse a range of domestic building representations. The analytics are used to investigate specific design and construction options and diagnose deliberate design faults or building regulation breaches incorporated into the models. Results of this project identify the key perspectives necessary to scope such a project; the critical aspects around which development of such a resource needs to articulate; and considers the separate evaluation processes required for the game development, the learning and teaching outcome and the project itself.

Keywords:

analytics, domestic construction, educational technology, video game engines

1 Introduction

Two recent reviews of undergraduate education in Australia identified that construction technology constitutes more than 20% of the first year architecture degree (Ostwald and Williams, 2008:126) and 25% of the building degree curriculum content (Williams *et al.*, 2009:20). Understanding construction technology remains a significant part of the core skills and competence requirements for all relevant professional accrediting bodies in building and construction (see for example, RICS, 2009). In the UK, construction is a key concept in The Quality Assurance Agency for Higher Education subject knowledge benchmark statements for construction, property and surveying (QAAHE, 2008:4). In Australia, the integration of

construction technology is identified explicitly as a Threshold Learning Outcome in the current Learning and Teaching Academic Standards project specific to building and construction (Newton and Goldsmith, 2011:5).

Traditionally, a significant component of construction technology curriculum has been delivered through exposure to work-based learning, project-based assessment drawn from contemporary industry practice and site visits to building projects currently under construction. The purpose of these forms of curriculum is to enable students to observe the process and technology of construction work in action. However, as class sizes increase, occupational health and safety regulations are tightened, potential site locations become more distant and the temporal nature of construction means there is only ever a minimal window of opportunity to witness particular aspects of technology, it has become increasingly infeasible to provide direct student exposure to the broad practices of construction technology in a realistic setting (Mills *et al.*, 2006). Equivalent difficulties face all vocational education programs in the built environment, where the practice situation involves dangerous and/or expensive process/technology contexts.

In such situations, the potential of replacing direct student exposure with a virtual simulation is apparent. In construction technology education, for instance, a number of previous initiatives have utilised a mix of Computer-Aided Design (CAD), QuickTime VR, video and multimedia as virtual substitutes for actual site visits (Horne and Thompson, 2008; Ellis *et al.*, 2006). Such initiatives certainly provide useful illustrations of the technical knowledge required, including (though generally indirectly) illustrations of relevant technical skills such as the scheduling of construction work tasks, project team management, and analysis of design defects. However, where knowledge-based learning generally can quite readily be demonstrated and assessed through written and oral tests, skill-based learning (competence) requires the student to practice and demonstrate actual activities in authentic situations.

Competence is fundamentally about the assessment of an individual's capacity to perform certain professional tasks in given situations in a particular way (Cowan *et al.*, 2007). Currently neither actual nor virtual site visits are, of themselves, sufficiently interactive for competence-based learning outcomes then to be demonstrated by the student or directly assessed by the teacher. The question of how students might practice and demonstrate competence in core discipline-specific skills (such as construction technology), particularly where such skills are best exercised in a difficult practice setting (such as a construction site), is yet to be resolved adequately.

A classic approach to competence assessment in architecture is the design studio, in engineering it is typically the testing lab, and in other fields such as medicine it is the clinical placement. In building and construction technology one equivalent approach has been to create a form of, so-called, 'constructionarium' (Ahearn *et al.*, 2005). A constructionarium is a controlled site setting where students under supervision work in teams to produce construction outcomes that range from building discrete brick walls, to short-span bridges and even simple buildings. Students experience, practice and can demonstrate (ie. be assessed on) the technical, process and managerial aspects of these construction activities. However, whilst they provide excellent learning experiences, the significant material and organisational costs associated with such projects renders them entirely impractical to apply across the curriculum more broadly and/or to large student cohorts.

One possibility is to replicate the constructionarium approach on a smaller scale and have students construct, say, 1:10 scale-models of buildings or their components (see, for example, Forsythe, 2009). Figure 1a illustrates one example of how first year students can use model building to demonstrate their competence in construction technology. It employs relatively sophisticated model-building skills to represent the technical and relational construction technologies of a typical domestic construction in Australia.

Figure 1a. A student 1:10 scale model outcome for a typical domestic construction exercise

Figure 1b. Another 1:10 scale model outcome that represents less sophisticated modelling skills

The use of such models is certainly a more viable exercise than actual site work, but its utility as a teaching method often depends as much on the model-building skills of the student as it does on their technical competence in construction technology. For example, Figure 1b illustrates another example of first year use of model building to demonstrate competence in construction technology. In this case the quality of the model building is far less sophisticated. It uses crude material representations (such as lego-bricks) that make it more difficult to demonstrate and assess the technical understanding of construction. This quality of modelling also makes it impractical to use the model as any basis for an analysis of the design and construction choices being made, through consideration of wind-loading/bracing, minimum spacing of rafters, effective timber jointing details, etc.

The aim of this paper is to articulate a current project to design, develop and evaluate the use of virtual reality technology to replicate the controlled site-setting and actual-scale nature of a constructionarium exercise, but with the same viability advantages that physical modelling has over actual site work. A key objective of the project is to deliver a level of immersion and interactivity in/with the virtual reality system that is sufficient to enable core construction technology skills (for example, the scheduling of work or the analysis of design/construction defects) to be demonstrated and assessed effectively and directly through the use of the system.

2 Why Choose Serious Video Games?

The most sophisticated interactive virtual reality simulation environments with practical application to teaching and learning are to be found in video games. Video games use high performance graphics engines to render moving photo-realistic scenes in real-time and 3D along with the potential for associated surround-sound audio and tactile feedback to a user who controls the action with a variety of input devices. Figure 2 demonstrates the visual quality achievable in the Crytek CryENGINE®3 game.

Figure 2. Real-time Scene Rendering in CryENGINE®3 (Wu, 2010:15)

The ‘action’ is in fact variously controlled not only through input devices, but also by the particular rules and properties ‘coded’ into the video game by the developer. Such coded rules and properties are now extremely sophisticated, and many incorporate models of real-world mechanical behaviours (‘physics engines’) that simulate physical properties such as mass, gravity, velocity, volume, etc. in exceptional detail. Objects in such games can variously be opened, pushed, bent, lifted, broken and/or be used to trigger a myriad of other actions. Artificial intelligence and social dynamics are also now being modelled and incorporated into video games to simulate agency and group behaviour in different game ‘actors’.

What is particularly timely about the potential development of video games for learning and teaching, is the recent development in video game technology that has resulted in the ‘game engines’ themselves (the kernel of coding used to drive a collection of actual game implementations) being made available on an open-source basis. Even the most powerful game engines are now relatively cheap to acquire for teaching and learning purposes, are intentionally configured to allow third party modifications to be created and embedded seamlessly into the game engine, and are increasingly supported online by a significant and committed community of users and developers (referred to as ‘modders’).

Several examples of ‘serious video games’ (a serious video game is one designed for a primary purpose other than pure entertainment, such as for learning and teaching) have now been developed as modifications to game engines across a range of game genres. For example, ‘vehicle simulation engines’ have been used to train and test vehicle operators from fighter pilots to crane drivers (Rouvinen *et al.*, 2005); ‘strategy game engines’ are variously used for teamwork and project management training; ‘business simulation games’ model economic and manufacturing environments. The current research project has focussed on a specific genre of video game known as a ‘first person shooter’ (FPS) game. FPS games are characterised by the use of an avatar which allows the user to see and be seen as a person would conventionally occupy a space (ie. bound to one's own body). Other game genres take a more abstract form of engagement (such as command-driven controls) or tend to focus more on the interactions and communications across a social network (such as in Second Life) rather than exercising specific technical competences.

3 The Concept of an Analytics Engine

Analytics involves the use of computer technology to access, transform, store, analyse and monitor information extracted from a variety of typically very large databases. For a study of the design and construction of a domestic house, for example, the analytics might involve mining, harvesting, analysing and visualising a representative range of data relevant to the particular instance of domestic house under review. Analytics seeks to extract and/or generate data relevant to a particular decision at a particular point in time in a particular location. Data such as building construction materials, statutory planning instruments, building codes, construction costs, design details, etc. The sheer scope and size of existing data sets, both public and private, that might relate to any given construction project is already a matter for concern (Rumor *et al.*, 2008).

It is already possible to store and access a range of relevant data through Building Information Modelling (BIM) (see, for example, Eastman *et al.*, 2008). However, such information typically has to be pre-loaded into a model and the visualisation options available are then limited significantly by the CAD system itself. There are currency issues with any pre-loaded information and BIM is simply unable to make extensive use of the many and varied ‘live’ digital data streams increasingly available from video cameras, monitoring stations, laser scanning, geographic positioning systems, augmented reality and a multitude of web-enabled feeds. Last year alone, digital information grew to 988 exabytes. To be effective, any analytics must incorporate the same range of data sources otherwise available to the decision-maker, which includes data well beyond the capability of current BIM systems.

Our concept for an analytics engine is one where the full range of potential data sources can be accessed, interrogated and visualised in real-time. In that sense, an analytics engine for the design and construction of domestic houses would enable the user to completely construct and/or dismantle any instance of house in any site setting, to measure any physical property (from distance between rafters to the bending moments exerted in wall bracing due to wind forces), to inspect any design detail (including automatic sections), to reference current building regulations relevant to a particular situation, local authority planning legislation, weather records, etc., etc. – any source of information that might be of interest and relevance to the user.

The Crytek CryENGINE[®]2 game engine used for this research has all of that functionality potential. It is already the benchmark for graphical performance, with near-photorealism in indoor and wide-open outdoor environments and extra-ordinary real-time special effects. This graphics capability is generally considered in terms of the visual realism it promotes, but it also means that no part of the interaction needs to be pre-recorded (canned). Every scene is freshly generated and able to be generated in whatever form a particular set of context variables dictate, in full stereoscopic 3D if required, on the full complement of graphics devices (even, now, down to the iPhone[®]). In addition, the game engine is able to interface with a range of Application Programme Interfaces (API's) including the multitude of live data feeds. This means it is now possible to modify every property, behaviour and minutiae represented in a video game based on user controls, calculations that result from user input and external data feeds. This might include the introduction of random events such as construction delays to simulated outcomes, dynamically changing details based on changes to building codes and/or explicitly modelling uncertainty using visual techniques such as blurring.

The critical question for this research is: How might such an analytics engine concept be implemented using the Crytek CryENGINE[®]2 game engine, for the particular purpose of supporting the learning and teaching of domestic building design and construction?

4 A Prototype Video Game-Based Analytics Engine to Understand the Design and Construction of Domestic Buildings

The design and development of any serious video game needs to be evaluated not just as a game but as a learning technology. This requires the standard design and production process for video games to be broadened to include consideration of the learning context – within what Luckin (2008:449) terms a “learner centric ecology of resources”. New serious video game initiatives are beginning to temper just such an explicit and specific overarching design and evaluation framework (de Freitas and Jarvis, 2006). This framework takes the more general form of a structured and rigorous consideration of the context (including the resources available to deliver, access and support the game), learner specifics (including learner attributes and preferences), representation (the form or mode in which the content of the game is made manifest to the user – explicitly, implicitly, vicariously, etc.), and pedagogy (the theory and practice models that frame the learning activities) within which a learning technology is to be deployed.

A formal process of human factor analysis using focus groups and task analysis has been undertaken, along with an analysis of the learning needs of current students. For instance, the learning needs were assessed by reviewing the performance of several hundred students in their end-of-year examinations, to identify those topics where students were having problems and the typical mistakes they were making specific to construction technology. A small reference group of users has been established to trial prototype systems and evaluate various implementations. Formal evaluation of the current prototype is being conducted using a control group of students having no exposure to the video game, where the placebo is standard revision and tutorial support.

The prototype game implementation simulates the addition of each element of the construction process, from site excavation through to roofing. It is a multi-user environment where individual

avatars are able to wander around and over the construction work, examining design details and following construction processes.

For example, Figure 3 is a screen grab showing two students interacting with the reinforcement and formwork just prior to pouring the slab. They can see how the work has been prepared, measure the distance between reinforcement saddles, test the capacity of the steel reinforcement under foot, check waste-pipe penetrations through the slab against best-practice guides, etc.

Figure 3. Screen Grab of Prototype Video Game Just Prior to Pouring the Slab.

As Figure 4a illustrates, the user is able to interact with the construction at any point, including when temporary bracing is still in place and as particular details between, say, bricks and timber and concrete are finished. Please note, the domestic construction used in this exercise is identical to the one used for the model-building exercise shown in Figure 1b. A building no larger than a standard garage has been used for this exercise over several years in order to limit the size of the models students must produce. It is only when seen at relative life-size that the unnatural proportions of the dwelling becomes obvious. At any stage the user is able to interact with the model and demolish parts of it to expose design and construction details. The extent of the demolition is dependent on the natural physics of whether the user employs, say, just their body-weight, a sledge-hammer or a truck. Users are also able to check the sizes and spacing of timber members against building codes, analyse the implications of loads on different structural configurations, check construction steps against project programmes, etc.

One particular tool is illustrated in Figure 4b, where a section through another, more complex timber construction has been instigated by the user. The building is then slid apart across the line of the section and the ends of any affected members highlighted in red. This facility can then be used to check an actual (model) construction against a designed section detail provided in a set of

drawings. The exercise requires students to interpret and compare both the actual as-built and the design drawings. It can be used to demonstrate and test a students' competency in reading technical drawings and interpreting an as-built construction.

Figure 4a. Screen Grab of Prototype Video Game Just Prior to Removal of Temporary Bracing.

Figure 4b. Screen Grab of Prototype Video Game Showing Use of the Section Tool.

The current prototype can also be used to test a students' understanding of related issues, such as safe work practices, material storage and handling considerations, site security, environmental protection, wet-weather hazards, noise pollution, etc.

5 Research Methodology

The key strategy for this project is to harness a formalised and integrated approach to the design and production of learning and teaching technologies. The scoping of the project has been built around 4 discrete perspectives: the professional bodies that already operate competence-based standards in the building industry are involved to ensure that the mode and level of competence is appropriate to industry expectations; teaching institutions that offer courses in domestic construction are involved to determine the common threshold concepts that broadly need to be included within such a domestic construction technology subject; the key stakeholders in benchmarking national academic standards are involved to establish the broader context for an outcomes-based approach to assessment; and direct engagement with other professional learning contexts is included to determine the general scalability and alignment of this teaching and learning approach across the education sector.

The development of the video game has proceeded around 5 critical aspects: an integrated design and evaluation framework for learning and teaching technology development (including a variety of specific processes and methodologies), supported by a Steering Group of expert practitioners; extensive experience in the application of serious video game technology to building and construction education; detailed CAD models already developed to support the domestic

construction technology subject; previous experience in the design and use of role-play and scale-model building; and the commercial interactive multimedia development expertise of our project team and reference group specific to teaching and learning applications.

The game development will be evaluated in terms of both the technology and the learning and teaching. In terms of the technology, the system is being evaluated by a range of users including a formalised user/testing/development group comprising students and academics. Prototype versions are being made openly available with the offer of direct support to any institution that wishes to participate in the trials. The development of installation and training notes to support the game has been included in the project funding. There will be two distinct development cycles over a 24 month period, each of which coincides with the teaching session in which the domestic construction subject is delivered. At this point we are about to conclude the first cycle. The project reference group includes external, commercial serious game developers who will undertake their own technical review of the system.

The learning and teaching outcome will be evaluated using case study and quantitative analysis. The case study will involve questionnaires and interviews with student, staff and industry participants. This aspect of the evaluation will draw directly from the notion of an ecology of resources used as a design and evaluation framework for education technology (see, for example, Luckin, 2010). The quantitative analysis will monitor the performance of students in the end-of-session examinations for the domestic construction subject. The past performance of several hundred students will be used to benchmark the performance of those students who use the game and those students who do not. Past performance has been analysed to identify those aspects of the curriculum where students perform poorly in the examination, and the typical mistakes they are making. A self-nominating group of current students has now been exposed to different combinations of issues through the game evaluation process, and the performance of those students will be tracked through to their examination performance. The comparative performance of each student between their mid-year assessment task and the final examination will also be compared across the user group and the control group (those students who have no exposure to the game). All participants will remain anonymous to the course lecturer and assessor.

The project itself will include two external reviews by an expert in the design and development of new technology applications in higher education teaching and learning. The external review will capture the experiences and perceptions of the relevant students, academic staff, support staff, professional bodies, government agencies and project team and complement the internal and on-going project design and development reviews.

6 Context and Discussion

The particular opportunity offered by serious video games to situate learning within an authentic professional context aligns this project directly with the development of professional knowledge and competence. Any framework that promotes and improves our understanding of the sociocultural context of and for professional practice will contribute to the broader consideration of learning as a situated activity (Wenger, 1998). Of course situated cognition is not without its critics (Vosniadou, 2007), and an approach that is exclusively sociocultural would undoubtedly ignore key cognitive aspects of learning and teaching. The focus of this project is on competence-based learning and assessment. It presumes that knowledge-based learning is a

necessary precursor to skill-based learning. So, whilst we might never reach a definitive expression of competence in sociocultural terms alone, it seems equally inconceivable that competence is something that can ignore human dispositions and social constructs (Hager and Holland, 2006). The growing significance of competence in higher education requires that more urgent attention be given to how we might teach and assess skill-based learning in that sector. That is what this project primarily seeks to do.

In seeking to evaluate the efficacy of serious video games in a learning and teaching context, we must also guard against complacency in the face of seemingly ever increasing sophistication (and ‘reality’) in the simulation technologies available. Virtual reality technology is impressive, but it is patently not ‘reality’. The ‘experience’ of a construction site and the practice and demonstration of construction technology competences in a virtual environment does not equate in every respect to the same experiences and demonstrations on an actual construction site. The entailments of a virtual versus a real situation are both positive (the virtual situation can be controlled, is available, scalable, specific, etc.) and negative (the virtual situation is abstract, simplified, sanitised, etc.). This project will examine the strengths and weaknesses of serious video games as a replacement for actual construction project experience and physical model building/simulation.

In a similar vein, any learning performance improvement that might emerge from the trial of the video game must be qualified against the spike in enthusiasm, resources and the sheer novelty value of any innovation introduced into the classroom. The proof of any benefit as a learning and teaching technology will only come from a longitudinal study across large and heterogeneous student groups. However, critical to such an examination is that the implementation of the learning tool (the video game) is as representative of the technical potential as is practical at that time. Collection of longitudinal evidence has now commenced, but the more immediate goal of this project is to design and develop a viable implementation/example of video game technology with which to drive such a study. The current focus therefore is on integrating and testing the overarching design and evaluation framework derived from Luckin (2008) and de Freitas and Jarvis (2006).

7 Conclusion and Further Research

Understanding construction technology is fundamental to the study of building and construction. It demands knowledge, skills and capabilities that are becoming increasingly problematic to deliver using traditional means. The potential of virtual reality in such a situation is apparent. Video game technologies have developed to the point where the most powerful and graphically advanced game engines are themselves now openly available and specifically configured to be modified by users. The possibility of adopting serious video game technology to directly support teaching and learning in construction technology is now a very real and practical one.

The broad concept developed in this paper is for an application of video game technology in the role of an analytics engine: where the full range of relevant data sources pertaining to a particular instance of domestic construction can be accessed, interrogated and visualised automatically. A prototype video game-based analytics engine has been developed using the Crytek CryENGINE[®]2 specific to teaching and learning domestic construction. That prototype has been described and its potential considered. A critical issue is the design and evaluation framework

being adopted to ensure the technology is developed and incorporated as part of a learner centric ecology of resources. The research methodology is specifically framed to challenge and inform that design and evaluation framework.

This paper highlights the four discrete perspectives necessary to scope such a project (professional bodies, teaching institutions, national academic standards agencies and cross-sector learning contexts). It identifies the critical aspects around which development of such a resource needs to articulate (an integrated design and development framework, steering group of expert practitioners, serious video game experience, detailed digital models, experience in role-play and other forms of simulation and commercial interactive multimedia expertise). Separate evaluation processes are also considered for the game development, learning and teaching outcome and the project itself.

The need for some qualification of the claims and achievements of any such project is recognised, until such time as a broad-base of evidence over time has been achieved. In consequence, the paper takes a conservative stance on the potential of the technology and the current prototype game. Ultimately, however, the vision is for a video game where students will be able to demonstrate the full range of technical competence expected of them (mapping the construction process, planning the sequence of tasks, selecting a viable configuration of materials and design options, ensuring compliance with relevant building codes and regulations, coordinating the construction activities, teamwork, etc.).

Abstract:

Productivity growth is probably the single most important indicator of an economy's health. In the UK construction industry the majority of waste is generated throughout the lifecycle of a building mainly due to limited accessibility to existing information. The use of Information Communication Technology (ICT) has proven instrumental in creating productivity gains within global markets, for example, through reduced transaction costs, scalability, and fast, reliable information flows, enhanced online collaboration tools and new ways to market goods and services. This paper will identify how future services such as, cloud computing and Build Information Modeling (BIM), can enable cost savings to the building industry by contributing to an increase in productivity through using open standards. The paper also identifies a working progress methodology section that has evolved from the results of the survey techniques used to date, based on cloud computing and BIM. The final section of the paper, uses two case studies to emphasize the potential cost savings benefits for the UK construction industry in implementing cloud computing and BIM.

Keywords:

cloud computing, construction, building information modeling, open standards, interoperability.

1 Introduction

Widespread deployment and use of interoperable technology applications, also called BIM has been identified by National Institute of Standards and Technology in the U.S. as a key activity for advancing construction efficiency and improving quality, timeliness, cost-effectiveness, and sustainability of construction projects (Huang *et al*, 2009). Goodrum and Haas (2002) identified those activities that have experienced a significant change in equipment and material technology benefit from greater productivity improvements. Teicholz (2004) believes the reasons for the decline in labour productivity are lack of R&D spending, fragmentation within the industry, and declining real wage rates. Teicholz also notes that despite the fact that there has been a significant adoption of new ICT by the construction industry over the past 35 years, these applications tend not to be integrated with other systems and therefore do not permit improved collaboration by the project team.

Alshawhi (2007) identified that isolated investment in ICT may satisfy a particular downstream business process, but its overall contribution to the business may not be significant. Alshawhi attributes this problem to the business-pull and technology-push paradigms where organisations respond to the needs of the marketplace through the deployment of relevant ICT, whereas the latter provides organizations with new technology-based business opportunities that can lead to new innovations. Hecht (2008) relates much of the waste that is generated throughout the life-cycle of a building to the result of people not having access to information that others have created. Hecht emphasises that insufficient information results in waste, and waste costs money, whether the waste comes from change order requests during construction, engineering errors, manual re-entry of data, redundant data collection, unnecessary meetings, mistakes in component dimensions or quantities, or over design to allow for uncertainty. All such waste translates into wasted natural resources. McGraw Hill Construction (2007) associated the concerns about productivity by owners and industry groups with the level of waste resulting from a lack of interoperability and that the industry generally perceives lack of interoperability as an impediment to improving productivity.

This paper will highlight the benefits of increasing productivity through implementing cloud computing and BIM. The paper identifies the structure of a working progress methodology, which is based on several survey techniques in investigating how to apply an integrated process based on exchanging information through using the vehicles of cloud computing and BIM. In further justifying the need to investigate cloud computing and BIM, the paper highlights two selected case studies to emphasize the cost saving benefits of using such vehicles in the construction industry.

2 Interoperable Design Solutions

2.1 Interoperability

Gallaher *et al*. (2004) identified that interoperability issues occur creating a fragmented business process and organisational structure. It is estimated that the cost of inadequate interoperability in the U.S capital facilities industry is \$15.8 billion per year. In 2002, the value of capital facilities set in place in the U.S. was \$374 billion. The magnitude of this figure suggests that even small improvements in efficiency potentially represent significant economic benefits. In recognising

that ICT has the potential to revolutionise the construction industry and streamline historically fragmented operations, Gallaher *et al.* states that tools, such as computer-aided drafting technologies, 3-D modelling technologies and a host of Internet and standards-based design and project collaboration technologies can reduce the fragmented nature of the industry. However, the problems associated with not being able to manage and communicate electronic product and project data between collaborating firms and within individual companies are compounded by the fact that a large number of small companies have not adopted advanced ICT.

Eastman *et al.* (2008) recognised that no single computer application can support all of the tasks associated with building design and production. Interoperability was highlighted by Eastman *et al.* because it depicts the need to pass data between applications, allowing multiple types of experts and applications to contribute to the work at hand. McGraw Hill Construction (2007) defined interoperability in a generic sense, as the ability to manage and communicate electronic product and project data among collaborating firms. Beyond the technological aspect, it is the ability to implement and manage collaborative relationships among members of cross-disciplinary build teams, that enables integrated project execution. In relation to project life-cycle, McGraw Hill identifies that the traditional method generally focuses its greatest amount of effort during the construction documentation phase, in contrast to the integrated approach, whereas the team members work closely together during the design phase, resulting in a greater ability to save costs before the construction process commences. In reference to this idea, McGraw Hill acknowledges that, in order to reap the full benefits of BIM's ability to promote integrated project delivery, build team members will increasingly need to have interoperable solutions. Figure 1 shows BIM's ability to control costs by reducing the cost of design from construction documents to the early design stage.

Figure 1. Earlier Decision Making through BIM Improves Ability to Control Costs (Source: McGraw Hill, 2007)

2.2 BIM and Open Standards

Smith and Tardif (2009) viewed interoperability as a foundational technology for greater efficiency and productivity in the building industry, similar to the Universal Product Code system, which is used for greater efficiency and productivity in the consumer product industry. However, Smith and Tardif also acknowledge that although interoperability is important, it is

only one of the many challenges facing the industry. Smith and Tardif identified buildingSMART Alliance, formally International Alliance for Interoperability, a council for the National Institute of Building Sciences, as a major industry standard body whose early project 'open-standard data format' otherwise known as Industry Foundation Classes (IFC) was deigned to facilitate interoperability by fostering the use of standardisation that is useable and accessible to all disciplines. Bew and Underwood (2009) credited BIM's evolution to early product modeling, such as the Standard for the Exchange of Product model (STEP). Bew and Underwood acknowledged that in 1983 IFC-STEP emerged to define product modeling as the long term ambition to improve the communication of engineering information (including manufacturing, ship building and construction) and to enable integration through the co-ordination of open standards for data exchange and sharing.

Smith (2007) underlined that the concept of BIM is to build a building virtually, prior to building it physically, in order to work out problems, and simulate and analyse potential impacts. Smith stressed that in reality all the information for a building already exists electronically and that this is the catalyst which makes implementing BIM a possibility. Waste will be minimised on-site and products will be delivered when needed, more components will be built and pre-assembled off site in controlled environments. The completed model will be the main source for planning and executing changes throughout the life of the facility; it will be tested and updated to validate compliance with the original design intent and energy usage. Hecht (2008) emphasised that the "I" in BIM is not about automating paper-based processes but about synchronising information across applications to speed up workflows and enable decision support, data bases, and purpose-driven content sharing. Hecht is of the opinion that in order to address the business issues confronting the global building industry, any vendor's BIM needs to interoperate across the internet with a wide range of other software solutions, providing a reliable basis for tracking and making decisions during the building's life-cycle.

2.3 Cloud Computing

Armburst *et al.* (2009) defined cloud computing, as both the applications delivered as a service over the internet and the hardware and systems software in data centres that provide those services. Onuma (2010) recognises that the internet moves in real-time and that computer devices, coupled with cloud-based tools, should make information more accessible to users. In a BIM context, Onuma acknowledges that traditionally exporting a file from application A, and then importing the file into application B, was the industry norm for sharing data between applications. However, it resulted in creating multiple copies of data. The identified solution is 'Service Oriented Architecture' where data can remain on application A and be used or modified by application B (or other applications). For Onuma this approach allows the user to access pertinent BIM data enabling BIM model views to be shared in small BIM data chunks. Kurtalj (2011) defined Mashups as a way to integrate into a common system various products and services. For example, adding Google Map with buildings scattered around the world, it is possible when clicking on the building, for a pop-up with a Building Management Systems (BMS) on that particular building to be accessed. The Mashup concept is highlighted by Kurtalj in relation to Building Automated Systems (BAS) for integrating data points and services from various networks into the same classes/objects infrastructure usable through the cloud model. Instead of translating the data from one protocol to another they can all be processed in the same script, as well as returning the data results back to the very network in its native language (plug-

ins). BAS and BMS can greatly improve the energy conservation of building operating and maintenance especially by implementing a centralised heterogeneous network ‘cloud.’ By exchanging information from interoperable energy consumption applications with 5D estimating BIM via the internet, the potential exists for predicting early building performance costs which would produce alternative economical designs.

3 Research Methodology (Triangulation of Data)

The formation of the research methodology has evolved from a 2009 cloud computing survey questionnaire, which was based on drivers, barriers and benefits of cloud computing in construction. The majority of the 90 respondents questioned in the survey were in aware of the benefits and upon further analysis BIM, accountancy, and project management applications were identified as the most beneficial services to be implemented as a cloud-based collaboration system (Hore, *et al*, 2010). In lieu of the cloud survey results, the opinions within a focus group comprising of 10 vendors in the Irish construction market-place were analysed on such topics as; security concerns relating to cloud computing, the potential development of a hybrid cloud for the group, and the issue of not being able to recode software that was not cloud compatible. The concept of implementing a cloud network was supported by the group. However a significant number of vendors had concerns for disaster recovery.

In review of the results extracted from the survey questionnaire and the focus group; a Delphi questionnaire was designed. The 16 international experts that were interviewed were chosen based on their knowledge or usage of construction informatics. The questions related to such topics as; the potential for developing a cloud service based on combining three identified applications of BIM, accountancy, and project management. The overall results indicated that the construction industry must become more like manufacturing, as there needs to be standard deliverables. The experts also acknowledged that the key to an integrated BIM process is based on a common database such as, a ‘cloud platform.’ The experts’ main concerns included security, vendor reliability and recovering data. The issue of whether accountancy and project management applications were the most appropriate for the collaboration service was inconclusive. However, BIM was recognised as being beneficial due to its ability to provide higher quality of information resulting in faster business decisions (Redmond *et al*, 2011)

The next round of the Delphi questionnaire will exam the same 16 international experts based on the categories identified from the previous surveys; main survey, focus group, and the initial Delphi questionnaire. The final stage of the primary research will be the semi-structured interviews. It is envisioned that a ‘Cloud BIM’ service will be recognised by interviewing ‘experts’ directly based on the categories identified from the data collated from the Delphi questionnaire. This type of methodology is referred to as ‘cross method triangulation,’ which refers to the use of two or more methods in a single piece of research (Hurmerinta-Peltomaki and Nummela, 2004). The applied approach to developing questions for this research is based on a theory known as ‘Grounded theory’ which essentially identifies and categories elements in order to explore their connections (Sayre, 2001). Figure 2 demonstrates graphically the sequence of questioning and relates each aspect with its associated path, such as the main survey questionnaire being referred to as a linear approach connected with developing theoretical propositions. The three stages, comprising focus groups, Delphi questionnaires, and semi-

structured interviews, are all associated with applying logic in practice, following a more qualitative subjectivist approach. It is anticipated that all topics will be categorized, refined and revisited through each of the stages in order to define the fastest and cheapest method of exchanging information through a cloud platform using BIM applications based on open standards.

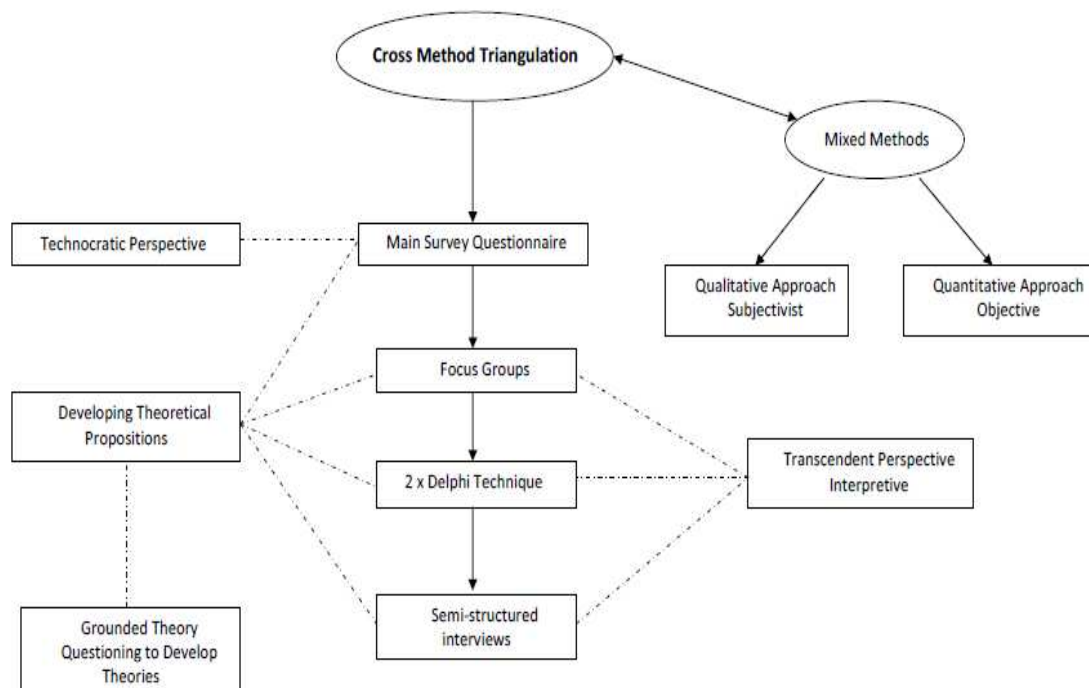

Figure 2. Research Methodology (Triangulation of data)

4 Findings and Discussion

4.1 Case Studies

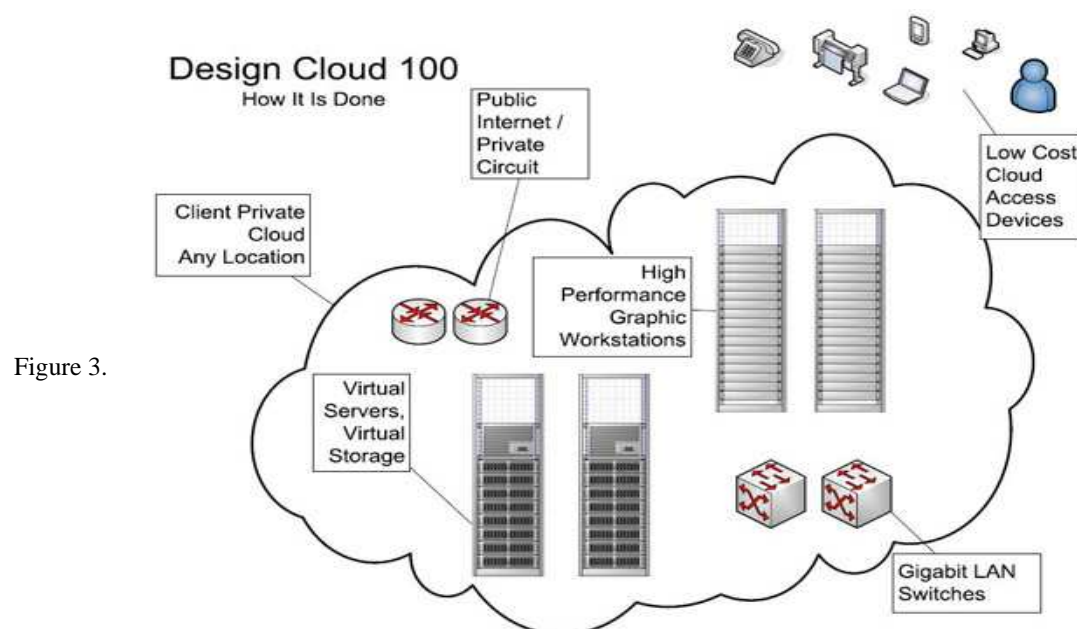

The following case studies have been chosen to highlight the cost saving benefits of using cloud computing and BIM in the construction industry. The first case study focuses on a small to medium size architectural firm using ‘Cloud BIM’ to assist in reducing costs in hardware expenses, enhance collaboration with external consultants, and have full mobility through a high performance workstation. The second case study is based on a construction firm, ‘Bechtel.’ This case study examines the capabilities of reducing infrastructure costs by adopting an architecture that creates a legacy free infrastructure through enabling virtualisation and horizontal connections to other operating systems.

4.2 Case Study 1: High Performance Graphical Workstations

France (2010) acknowledges that most of the current discussion around cloud computing has been dealing with servers (or back-end systems); only recently have businesses begun to put their desktops and workstations into the cloud. France stated in 2010 that their private cloud is the first Architecture, Engineering and Construction workstation cloud in production and is on track to

reduce their workstation and laptop hardware expenses by 67% (\$2m) over the next 10 years. France attributes the business benefits of workstation clouds to BIM, as designers are now able to construct a fully documented, 3D building on a computer before they actually build it on-site. This process requires a lot of computer power and overcoming obstacles, such as, (i) growing desktop computing needs – applications which require a lot of simulation, analysis, rendering, and 3D modelling, in order, to design buildings, each year. France's company spends between \$250,000 - \$300,000 on refreshing laptops with more software capabilities. Based on the cloud access devices, new laptops were purchased for less than \$1000 and only when required, (ii) collaborating with outside firms on the same model – with the widespread usage of BIM cloud technology can define real-time collaboration between firms allowing external consultants' employees to develop on the same models, and (iii) full mobility – the high performance workstation enables laptop connection through a Remote Desktop Protocol to have full usage of resources such as a 20MB internet connection.

In continuation of driving down costs and greatly increasing operational capabilities such as “instant” provisioning, disaster recovery, and business continuity, all servers were placed into a virtual infrastructure. Technically the workstations were not virtualised; they were identified as more of a utility that creates the ability to share Windows 7 64-bit operating system with many users at the same time. This process is used for adapting the servers. Storage capability had to be reconfigured for the desktop virtualisation products due to the inability to virtualise the Graphic Processing Unit (GPU), which would have led to a slower performance. The model for GPU computing is to use a Computer Processing Unit (CPU) together in a heterogeneous co-processing mode meaning the sequential part of the applications run on the CPU and the computationally intensive part is accelerated by the GPU.

Implementation diagram of the HPGW cloud (Source: France, 2010)

France's solution was to use a hybrid approach, turning a single-user workstation into a multi-user workstation (workstation server). To the end-users it represented virtualisation and it was cloud based; to the IT staff it was a piece of shared hardware that enabled 10 people to share this workstation. Figure 3 shows the implementation of the virtualised High Performance Graphical Workstations (HPGWs). By changing to cloud computing France's firm (of 225 people) can now provide design services on 20 HPGW cloud computers and the workstations will not need to be refreshed every two years. The result of this action will mean most of the computing load will be moved off the laptops, estimating a spending cost of \$1m over 10 years in contrast to \$3m due to purchasing desktop hardware for the same period.

4.3 Case Study 2: Transforming ICT Systems based on Cloud Computing

In 2009, PriceWaterHouseCoopers (PwC) published a quarterly journal based on the real promise of cloud computing. Within this report PwC analysed Bechtel, a construction company with an elastic workforce of 44,000 employees and revenue of \$31.4 billion in 2008. Bechtel had made a massive leap towards cloud computing after identifying the problems associated with traditional ICT vertical stacks. The three principal layers of a typical traditional stack are: infrastructure, including compute, storage, and networking assets; application workloads that enable business processes; and end-user devices, which provide the interfaces to access applications. This vertical technology delivered a solution with an acceptable performance. The hardware, application software, and middleware tools are built to order for the application requirements. However, this system creates an instant legacy problem of interdependencies among process logic, data logic, integration logic, compute capacity, storage capacity, and networking functionality. The problems associated with creating interdependencies with standalone stacks becomes evident from the complexity of making changes to individual layers to the increased cost of support and maintenance due to knowledge becoming scarce. The typical ICT environment today is a collection of hundreds or even thousands of tightly coupled vertical stacks integrated with each other.

Bechtel transformed its ICT systems and processes based on best practices of cloud computing providers and in doing so moved towards a more cost efficient, high performance computing. PwC describes this move as Evergreen ICT. Evergreen ICT is an infrastructure architecture designed to deliver loose coupling between distinct layers of ICT stacks, and transition of ICT operations from manual to automate through intelligent software. The critical ingredient for Evergreen ICT architecture is the loose coupling between hardware or middleware and application workloads. The software sits between the raw computation, storage, network environment and the applications known as the software mediation layer. Figure 4 illustrates how the software mediation layer can decouple infrastructure and support the automation of the ICT processes of provisioning, management, and orchestration. In practice, this means that the mediation layer should be configurable to emulate whatever application programming interfaces to which the application were written; for example, Windows and various versions of UNIX.

In conclusion the history of ICT has been dominated by build-to-order systems, resulting in legacy environments. However, the adoption of architecture that can create loose coupling between infrastructure and applications will create legacy-free infrastructures. As Bechtel has indicated, it does not have to happen in one big move, but rather, a process that begins with creating standardised infrastructure, onto which compliant workloads can be moved and over

time organisations can move more complex application workloads to this infrastructure as software mediation (virtualisation) technology matures (PriceWaterHouseCoopers, 2009). Figure 4 illustrates the decoupling of the middleware that enables virtualisation and horizontal connections to other operating systems.

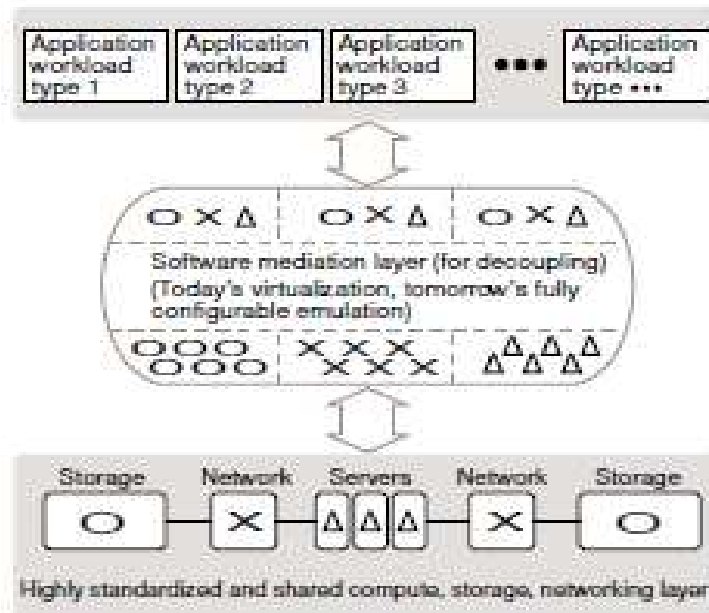

Figure 4. Software Mediation Layer (Source: PwC, 2009)

5 Conclusion and Further Research

The identification of the necessary tools that can successfully improve the performance of a building throughout its life-cycle has always been a challenge, which can be related to the lack of industry standards, inefficient collaboration tools, and design team member's inability to access interoperable applications. In section 2, the benefits of interoperability through passing data between applications, allowing multiple types of experts and applications to contribute to the work at hand was highlighted. The advantage of having a BIM model prior to construction was referred to as a process that minimizes waste on-site and enables products to be delivered when needed. However, in order for BIM to successfully integrate with various applications, open standards for data exchange and sharing would have to be co-ordinated. Section 2, also identified that by using a cloud platform for BIM, the potential exists for saving costs by exchanging information from interoperable energy consumption applications with estimating BIM software. The methodology section (section 3) highlighted the results of the three survey techniques undertaken to date; cloud computing survey, focus group and Delphi questionnaire. The full scope of the research will also include semi-structured interviews, in order, to full identify the reduced costs benefits of implementing cloud computing and BIM, into the construction industry. The cloud-based BIM study of a small to medium size architectural firm emphasized how using this technology enabled them to define real-time collaboration between firms on the same model and reduce hardware expenses by \$2m over a 10 year period. The ICT transformation of 'Betchel construction' from traditional standalone vertical stacks to cloud

computing enabled a more cost efficient and high performance computing by adopting an architecture that created loose coupling between infrastructure and applications. In conclusion, this paper has identified the potential cost savings of using services, such as cloud computing and BIM in providing an integrated project delivery. However, in relation to the methodology, further research is being undertaken to investigate the enhancing possibilities of exchanging information through a cloud platform using a BIM model to improve productivity in the UK construction industry.

Energy-led retrofitting of solid wall dwellings – technical and user perspectives on airtightness

Phil Banfill¹, Sophie Simpson¹, Victoria Haines², Becky Mallaband²

²Loughborough Design School, Loughborough University

Abstract:

Mechanical ventilation with heat recovery (MVHR) is increasingly being promoted in the UK as a means of reducing the CO₂ emissions from dwellings, and installers report growing activity in the retrofit market. In parallel with a survey of householder preferences and practices, the behaviour of a whole-house MVHR system installed in an experimental house, purpose built to typical 1930s standards, has been simulated. The range of air permeability values corresponded to those achieved in a retrofit upgrading process carried out on the house. In the house considered, air permeability, as measured in a 50 Pa pressurisation test, must be reduced below 5 m³/m².h for MVHR to make an overall energy and CO₂ saving. This required a level of disruption that would be unlikely to be tolerated by owners of solid wall dwellings.

Keywords:

airtightness, dwellings, householders attitudes, mechanical ventilation

1 Introduction

The UK has the oldest housing stock in the developed world (Energy Saving Trust, 2003). Of 25 million dwellings in the UK, 34% have solid walls and are responsible for 50% of the total UK domestic sector CO₂ emissions. In a typical unimproved UK solid wall dwelling the ventilation heat loss rate is approximately equal to the heat loss rate through the fabric (walls, roof and ground floor) so, in the context of Government targets of reducing CO₂ emissions from buildings, reducing this ventilation heat loss is attractive and the Energy Saving Trust (2005) emphasises the importance of improving the airtightness of dwellings. Since mechanical ventilation with heat recovery (MVHR) is an established contributor to achieving the zero carbon homes standard required by UK legislation for all new homes by 2016, including those reaching Passivhaus standards, there is an emerging market for MVHR in retrofit installations. However, it is much more difficult to achieve the required low levels of air permeability by retrofitting an existing dwelling than when building a new one, and it is not clear to what extent users and specifiers of retrofit MVHR systems realise how important the building's airtightness is in achieving the anticipated savings. Understanding the technical implications and the user perspectives on airtightness is therefore necessary to prevent inappropriate advice, potentially leading to undesirable disruption and expensive mistakes, being given.

This paper describes some of the work in progress as part of a consortium project entitled *Consumer appealing low energy technologies for building retrofitting* (CALEBRE -

www.calebre.org.uk), which aims to establish a validated, comprehensive refurbishment package for reducing UK domestic carbon emissions, that is acceptable and appealing to householders, and specifically targeted at UK owner occupied solid wall properties (classified as ‘hard-to-treat’). It is investigating a selection of technologies, informed by the reality of the user perspective, addressing such questions as the degree of disturbance that householders are prepared to tolerate during a refurbishment programme. Some of the retrofit solutions have been installed and are being evaluated in a newly-constructed test house (the E.ON 2016 House, Figure 1), specially built in 2008 to 1930s standards at Nottingham University. This house has cavity walls which are assumed to have similar performance, when the cavity is filled, to solid walls with external insulation, and there is no reason to expect the air permeability to be different in the two cases. This paper describes results in two main areas, (i) the importance (and difficulty) of achieving airtightness in reducing heat losses and CO₂ emissions from dwellings and (ii) homeowners’ perspectives on this aspect of the retrofitting of their homes.

2 Indoor air quality, ventilation and airtightness

2.1 Technical background

Ventilation is needed to dilute and remove pollutants produced indoors, such as moisture, body odours, cooking smells and volatile organic compounds, as well as to supply fresh outdoor air (Awbi, 2003). If moist air comes into contact with a cool surface, the local relative humidity increases, and when it exceeds 80% the risk of mould growth increases rapidly (Roulet, 2001). Any surfaces below the dew-point temperature will permit condensation to form, a serious problem with uninsulated external walls. The development of damp, mould and fungi can result in health and comfort issues for occupants, therefore it is important for the ventilation strategy to maintain RH levels between 30-70% (Carrer et al, 2001). This means that in general the ventilation rate is greater than that required merely to supply fresh air (Energy Saving Trust, 2003). For dwelling renovation, therefore, it is important to consider the ventilation strategy when implementing measures to improve the building airtightness to ensure there is no detrimental effect on occupant comfort or the building fabric.

The UK’s relatively mild climate means dwellings predominantly rely on uncontrolled natural ventilation. This does not guarantee a sufficient air change rate to maintain indoor air quality all year round, but allows excessive ventilation and heat loss in windy conditions. Until the recent drive towards low carbon housing, the airtightness of UK dwellings showed little improvement. In a survey of 471 dwellings (Stephen, 1998) those constructed between 1900-1930 had a mean air permeability just over 10 air changes per hour (ach⁻¹) at 50 Pa, measured by the pressure test (CIBSE, 2000). For a sample of houses built 1930-1960, it exceeded 15 ach⁻¹, while in the most recently constructed properties it had returned to 10 ach⁻¹. In other parts of Europe dwellings are much more airtight and mechanical ventilation (with or without heat recovery) is universal. It should be noted that the 50 Pa value, specified in standards, is different from the unpressurised infiltration rate that should be used in thermal energy calculations. Kronvall (1978) derived a ‘rule of thumb’ method in which the natural infiltration rate is 0.05 times the tested air change rate. In this paper, all measured air change rates and permeabilities are 50 Pa pressure test values.

Passivhaus standards (2011) specify 0.6 ach⁻¹ at 50 Pa and were developed to enable the design and construction of dwellings with annual heating or cooling energy consumption below 15

kWh/m² treated floor area. At this level, the ventilation system can address the space heating needs and a whole house MVHR system is an essential component of this strategy. Although strictly these standards apply only to new buildings, they are increasingly being implemented in refurbishment projects, and the first certified Passivhaus retrofit in the UK was recently achieved for a terraced Victorian property (Octavia Housing, 2011).

The heat recovered from the ventilation air by MVHR offers a modest contribution to CO₂ emissions savings. As a result the market for MVHR systems in the UK has been stimulated and in 2009 was estimated at 15000 units annually, worth £30million. Of this the retrofit sector accounts for a small but growing share of about 5% (Waddell, 2010). Since the effectiveness of an MVHR system depends on the correct balance between heat recovery efficiency, fan efficiency, air flow rate and building airtightness there is a technical challenge in using MVHR for retrofit. Since there was no prior information on this, the technical objective of this investigation was to establish the airtightness level that must be achieved in order for MVHR to have a significant effect on the CO₂ emissions, using both modelling and monitoring.

Macintosh and Steemers (2005) found differences between the expectations and reality for an MVHR system in housing in four areas:

Noise – disturbance from external noise and pollution should be improved, but residents in the study reported noise from inlet vents which was unwanted.

Perceived freshness – ventilated air may not be perceived as fresh as it is not at external temperature and no direct connection to the outside (for example via a window) was made by residents.

Perceived control – residents opened/closed windows much more frequently than they made adjustments to the MVHR controls.

Misunderstanding – residents misunderstood what the ventilation was for and when it should be used.

In light of this, the behavioural objective of the investigation in this paper was to compare the technical findings with user perspectives in order to identify acceptable ways forward.

2.2 User centred design background

For any new technology to be successful, it must be accepted by the end users and meet their needs. These needs include their social, emotional, practical and economic needs. For a technology such as MVHR, it is critical that it is considered in context of the built environment and the end users, that is householders. By taking a user centred design approach, it should be possible to explore the existing ventilation practices of householders and identify requirements for the technology that will meet these requirements in context. The principles of user centred design are generally accepted to be an early focus on users and tasks, empirical measurement and iterative design (Gould and Lewis 1985), leading to the design of useful, useable and desirable products. Preece et al. (2002) propose that providing “an easily accessible collection of gathered data” will help designers remain focused on user needs. Clear communication of requirements to designers and technologists in a way that is meaningful and relevant is therefore a crucial

component of user centred design. To this end, CALEBRE is taking a user led approach to understanding householders with the intention of ensuring that the resulting technologies are designed to be acceptable and appealing.

3 Research Methodology

3.1 Summary of the CALEBRE project

The CALEBRE project aims to develop a number of technologies suitable for retrofitting to solid wall dwellings. These are at various stages of completion and will be tested either in the laboratory or in service in the E.ON 2016 house. In addition to the work described in this paper, there are a number of technological workpackages, which can be summarised as follows:

Develop an electric air-source heat pump, able to deliver hot enough water to make it suitable for replacing the boiler in an existing central heating system.

Develop a gas-fired air-source heat pump, able to deliver hot enough water to make it suitable for replacing the boiler in an existing central heating system.

Develop vacuum double and triple glazing units, able to achieve U-values of $0.33 \text{ W/m}^2\text{K}$ or less, suitable for use in conventional windows.

Develop advanced surface treatments for internal walls, with hygrothermal properties able to smooth the changes in air temperature and relative humidity.

In addition, the project will explore the market development issues associated with mass production of these novel technologies and develop a prototype selection tool, informed by the identified needs of homeowners. The project has a strong consumer focus and a group of householders has been recruited to participate in the evaluation of the technologies and their implications for user behaviour and performance in service.

3.2 Airtightness measures

Air permeability tests using the 50 Pa fan pressurisation technique (CIBSE, 2000) were carried out on the E.ON 2016 house in its initial state and following each stage of the application of a series of retrofit solutions (Table 1), installed over several months with the aim of reducing the level of uncontrolled ventilation. This provided a series of measured permeability values which could inform the infiltration value used in a dynamic thermal model of the house to assess the impact on the annual energy consumption and CO_2 emissions. Some of the upgrades to the external fabric and glazing have multiple benefits in that they contribute to reduced infiltration rates as well as conduction losses. Measuring the changes in the building's air permeability allows the combined effect of these improvements to be assessed as a series of retrofit measures by updating these properties simultaneously in the thermal model.

3.3 Dynamic Thermal Modelling

Dynamic thermal modelling software (IES Virtual Environment) was used to build a model of the E.ON 2016 house (Figure 1) to simulate a year's operation and calculate the annual energy consumption and CO_2 emissions. Details of the building geometry and orientation were input

using the architectural drawings to create zones corresponding to each room and represent the building. The Nottingham Test Reference Year weather file (CIBSE, 2008) was used to simulate local climatic data.

Figure 1 E.ON 2016 house at The University of Nottingham and the IES VE Dynamic Thermal Model

The operational parameters for each room type were derived from the National Calculation Methodology database (NCM, 2010) to develop a set of templates representing the occupied house, specifying heating set-points, domestic hot water consumption and internal gains (lighting, equipment and occupancy), as well as diversity profiles set up to represent daily and weekly variations in these values.

These parameters were consistent for all the analyses so that the variations in energy performance would be attributable to the ventilation strategy and the thermal properties of the building. The thermal modelling assumes that there are no changes in the internal conditions before or after the application of the retrofit measures, and that occupants do not take the benefit of higher living temperatures. This may be wrong, as research into this ‘rebound effect’ shows (e.g. Sorrell, 2009), but will not be considered further here.

Construction templates were created defining both the internal and external constructions, and performance characteristics. This allowed the changes in U-value between the initial base case house, as built to 1930s construction standards, and the thermally upgraded construction, as per the improvement work carried out as part of the retrofit process, to be replicated in the E.ON 2016 dynamic thermal model. This would simulate the differences in conduction losses associated with the improved glazing and building fabric.

3.4 Understanding of User Requirements

To understand the requirements of the users in context, twenty households (with 66 permanent occupants) were recruited to take part in a series of data collection activities. Each household lived in an owner occupied, solid wall house in the East Midlands region of the UK. A purposive sampling approach was taken, to ensure inclusion of a range of house types (detached, semi-detached, link, mid and end terraced), household types (single, couples, families with young, older and grown up children), participant age ranges (28 – 80 years old), income bands (under

£10,000pa – over £70,000pa) and location (urban, suburban, rural). While not intended to be a statistically representative sample, it allowed detailed exploration of a snapshot of different domestic situations.

Two in-depth interviews were undertaken with all adult household members wherever possible to ensure a whole household perspective. The first interview explored reasons for buying the property, improvements made to the house and issues relating to these (who did the work, levels of disruption, approximate cost, etc). These were drawn up with the householders using an innovative ‘timeline tool’, reported in more detail in Haines et al (2010). Issues relating to comfort and home improvement aspirations were also covered. In the second interview, attitudes towards energy saving were explored, the CALEBRE technologies were described to the householders and initial responses obtained. Questions were then asked about the householders’ various practices in the home that related to the design of the technologies. These were intentionally focused on the householders and their home lives to ensure a relevant and engaging conversation, rather than a more formal question and answer session. Finally a tour was made of the home to see in detail aspects of the house that had been mentioned in the discussions, as well as to take a photographic record of the various features. Digital audio recordings from these interviews were transcribed and analysed using NVivo 9. Conversational extracts relating to ventilation and related practices were analysed in detail and the key findings are presented in this paper.

4 Results and Discussion

4.1 Air permeability

Each set of improvement measures applied to the E.ON 2016 house contributed to a reduction in the building’s air permeability, but with variable success (Table 1). In its original state the house was very leaky and the extensive stage 1 improvements were expected to significantly reduce the measured air permeability but succeeded in reducing it only from 15.57 to 14.31 m³/m².h. The relationship between permeability in m³/m².h and air change rate is specific to the geometry of the building: in this case 15.57 m³/m².h = 14.85 ach⁻¹. Noting the inconsistency with air change rates mentioned earlier, we report permeability values here because they are familiar to UK professionals. Inspection revealed that the draught-proofing had been poorly applied to the windows and doors, often with an incomplete seal around the perimeter of the component, and installing the MVHR system had created new gaps in the building envelope and duct connections to the rooms, permitting uncontrolled airflow. In stage 2 the draught-proofing was re-done and extended to the remaining doors and windows, reaching 9.84 m³/m².h. The building air permeability was further reduced by the two remaining stages, culminating in the final measure of sealing and insulating the ground floor, which achieved the final building air permeability value of 5 m³/m².h at 50 Pa.

Much effort and cost was needed to reduce the air permeability and the research team were surprised at how poor was the workmanship in the initial stages of draught-proofing, undertaken professionally to current industry standards. Gaps were left around doors and previously installed insulation disturbed by later work. The final stage was especially disruptive and involved lifting floor coverings and furniture before installing a membrane over the timber floor. The total cost

of draught-proofing exceeded £12000, and with the MVHR installation costing £6000 this is unlikely to be economic.

While sealing a house is perceived as a simple task, it is in fact much more challenging because of the care and attention to detail needed by the workforce. Air permeability is made up of a myriad of entry points in the fabric, which can be created by oversize holes for pipes and wiring, irregular gaps between new windows and brickwork openings, gaps between walls / floors and walls / ceilings, etc (Energy Saving Trust, 2005). Suspended timber ground floors can be a particular problem and in this case success was achieved by installing a membrane across the boarding, which was dressed up behind the skirting boards.

Table 1. E.ON 2016 house measured air permeability values

Stage	Air permeability at 50Pa ($\text{m}^3/\text{m}^2\cdot\text{h}$)	Description of work
As built	15.57	Single glazed windows Uninsulated walls, floor and roof space No draught-proofing
1	14.31	Double glazing installed Insulation applied to walls and loft Draught-proofing applied to windows (excluding kitchen, bathroom and WC) and doors Installation of whole house MVHR system
2	9.84	Kitchen, bathroom, WC windows and undercroft trap-door draught-proofed Draught-proofing throughout house re-installed Window trickle vents blocked up
3	8.60	Service risers sealed Pipework penetrations sealed (radiators, water pipes etc.) Sealing around boiler flue Covers fitted to door locks Kitchen fan removed and bricked up
4	5	Suspended timber ground floor insulated and sealed

4.2 Heat losses, energy consumption and CO₂ emissions

Full details of the dynamic thermal simulation and energy modelling have been reported elsewhere (Banfill et al, 2011) and are summarised here. Figure 2 details the disaggregated loads on the heating system at the time the peak space heating load occurs in the dynamic analyses. Note that, as the final retrofit measure is applied the peak load occurs at a different time of year. The results show the expected significant reduction in energy consumption as a result of the work, but since the focus of this paper is on airtightness, these will not be considered further. Note that measured thermal energy data is not yet available, since performance monitoring is still in progress. Comparing the performance of the building after stage 4 with the base case as built shows an overall 71% reduction in total annual building energy consumption from the base case.

This takes into account the energy associated with the space heating, domestic hot water, auxiliary (fans and pumps), lighting and equipment.

To investigate the effect of MVHR alone (i.e. separate from the other measures listed in table 1), a modelling study starting from a naturally ventilated base case of $10 \text{ m}^3/\text{m}^2\cdot\text{h}$ (based on the recommended ventilation rate as advised by BRE Digest 398, where Kronvall's rule of thumb has been used to determine an equivalent air permeability value), simulated its effect on energy and CO_2 emissions at successively reduced air change rates, culminating in the Passivhaus standard of $0.63 \text{ m}^3/\text{m}^2\cdot\text{h}$ (0.6 ach^{-1}) and the results are given in table 2.

Figure 2 E.ON 2016 House: breakdown of heat loss at peak space heating load

It may be recalled that stage 4 of the retrofitting measures achieved a 50 Pa air permeability of $5 \text{ m}^3/\text{m}^2\cdot\text{h}$. At this level the annual energy consumption is barely reduced and the CO_2 emissions are still above the unimproved house. Further improvements in air permeability would be necessary to effect a significant reduction in energy and CO_2 but even at $0.63 \text{ m}^3/\text{m}^2\cdot\text{h}$, the Passivhaus level, annual energy consumption is only 11.7% lower and CO_2 emissions are only 5.3% lower.

The carbon intensity of the electricity used to operate the MVHR system is about three times that of the gas used for heating and this means that achieving an overall reduction in the building's CO_2 emissions requires the space heating demand to be reduced by three times the electricity consumption of the MVHR system.

4.3 Householder preferences and practices

Achieving an airtight house may be a desirable approach from the perspective of saving heat loss and hence CO_2 but any system, particularly one that will be retrofitted, must meet the

householders' requirements or else it will not be appealing nor acceptable. The practices and preferences obtained from the householder interviews uncovered a range of issues that may result in an unappealing system, or one that works sub-optimally. These are discussed below. Whilst many of the homes had some double glazing and loft insulation, none had more advanced energy efficiency measures installed. None had attempted to actively reduce the air permeability of their home (although attempts to reduce draughts had been made through fitting double or secondary glazing, by using carpets and soft furnishings and by blocking up chimneys). None of the houses had an MVHR system.

Table 2. Impact of airtightness on modelled annual energy consumption and CO₂ emissions of the thermally upgraded E.ON 2016 house using an MVHR system specified to best practice standards.

Study	Annual space heating energy (kWh/m ²)	Annual auxiliary energy (kWh/m ²)	Total building annual energy consumption (kWh/m ²)	% change (energy)	Total building annual emissions (kg.CO ₂ /m ²)	% change (CO ₂)
10 m ³ /m ² .h naturally ventilated	65.7	9.6	126.9	0	44.6	0
10 m ³ /m ² .h with MVHR	76.4	10.8	138.8	+9.4%	47.4	+6.2%
7 m ³ /m ² .h with MVHR	66.3	10.8	128.8	+1.5%	45.4	+1.7%
5 m ³ /m ² .h with MVHR	62.9	11.4	125.9	-0.8%	45.0	+0.9%
3 m ³ /m ² .h with MVHR	56.5	11.4	119.5	-5.9%	43.8	-2.0%
1.05 m ³ /m ² .h with MVHR	50.3	11.4	113.3	-10.7%	42.6	-4.7%
0.63 m ³ /m ² .h with MVHR	49.0	11.4	112.0	-11.7%	42.3	-5.3%

4.3.1 Air flow and freshness

Many householders were keen to maintain air flow within their homes, even if it meant obvious heat loss. Current approaches to controlling air flow included opening and closing doors, windows or vents, or closing curtains to block off draughts. One participant spoke of the more refreshing “natural feeling of a breeze” (Male, age 29) and airtightness was seen as a negative issue: “I like to be able to breathe fresh air. I don’t know if I’d really want an airtight house” (Female, age 61). Associations were made with the environment within an aeroplane, with words such as “recycled”, “stale” and “manky” being used to describe their expectations of a mechanical ventilation system. When an MVHR system was explained to householders in more detail, the idea was more positively received (particularly in relation to some of the other

technologies presented) and so there is clearly potential for successful systems once the initial preconceptions are overcome.

4.3.2 Open fireplaces

Of the 20 houses surveyed as part of the project, 15 had some form of open chimney or vent for a wood burning stove. Of these houses, 9 of the householders said they would not be prepared to consider losing the functionality of all their fireplaces (even if they were able to keep the fireplace aesthetics). Some were prepared to lose the functionality of some of the fireplaces, but not all. The majority of households viewed the fireplace as an occasional ‘treat’ rather than the standard method of heating the home. Its use was described by one householder as “High days and holidays – not very often” (Female, age 51). However there were households in the sample that used their fireplaces every day during winter. Although householders may be aware that the fireplace inhibits the airtightness and increases draughts, they were still unwilling to remove its functionality and instead prefer to use temporary blocks for the chimney when it is not in use, as illustrated by this comment: “The only thing that would not be airtight...would be the fire place because there is no balloon in or cap or anything like that, so that can be quite draughty in winter, but we stick a black bag full of newspaper up there don’t we, when we’re not using it” (Male, age 29). Those householders that would be happy to lose the functionality of their chimney expressed a desire to keep the aesthetics of the traditional fireplace in order to maintain the period features of their home. Although some of the houses had fireplaces in upstairs rooms, none were used; when questioned, this was due to safety, and so could easily be made airtight.

4.3.3 Door opening practices

A retrofitted MVHR system is likely to require a good circulation of air within the home (as a more limited venting system will be easier and less disruptive to install) and so internal door opening practices were explored. Householders reported strong habitual practices, for example always closing certain doors at night time, or leaving doors ajar at certain times of the day. Reasons for habitually closing internal doors included to reduce internal noise (from other members of the household, or a striking clock), to stop dust circulating through the house, to keep pets and young children in particular areas of the house, for privacy or to keep light out, or to shut off part of the house, either when a child has grown up and moved away, or when only certain rooms are heated. This final practice was common in houses where householders did not heat their whole house every day (perhaps only doing so when guests were visiting) or to keep the heat from an open fire within a room for the “cosy family stuff” (Female, age 51). Internal doors were sometimes left open by householders as a regular practice, or were so poorly fitting that air would circulate past them easily even if closed: “When they do shut they have got gaps haven’t they” (Female, age 43).

4.3.4 Damp

Many of the householders had damp areas in their homes and used ventilation as a means to control humidity. This may be as a short term measure (e.g. after a shower) or longer term, with the regular use of a de-humidifier. Whilst many householders recognised they had a draughty house, there was a feeling that the draughts kept the house adequately ventilated and healthy. The need for a system to replace what occurred naturally was not recognised. Communicating the benefits of an airtight house with MVHR system is critical to win over these householders.

4.4 General discussion

Achieving airtightness is clearly important for reducing heat losses and CO₂ emissions and MVHR can contribute to savings but levels sufficiently low for MVHR to be effective are very difficult to achieve in older properties, as demonstrated by the number of stages needed for sealing the E.ON 2016 house. In addition, people have features in their older homes that mean airtightness is difficult to achieve, in particular open fireplaces that are used regularly in the winter. They may be willing to block these (using a balloon or similar) in the summer but this is not the time when it is needed.

Retrofitting an MVHR system will probably mean a reduced number of vents, because the likely whole house disruption that will be caused by a more integrated system is unwelcome to householders unless they are doing total renovations. However, our study of 20 households suggest that whole house renovation is uncommon other than at the time of purchase (and even then not all householders did this).

Attitudes towards an MVHR system are initially negative: people like fresh air in their home, which they feel is necessary to deal with issues like damp and condensation, as well as a perceived negative effect on health through germs being recirculated. When it was explained to them, householders were more positive about MVHR, appreciating that it could help their damp problems and that the same air was not recirculated, and so the benefits would need to be clearly communicated. However, people have habitual internal door opening / closing practices that mean that air flow within the house may be limited (closing doors for privacy, keeping pets or children contained, etc), which could limit the effectiveness of an MVHR system.

5 Conclusion and Further Research

Airtightness is a crucial factor in achieving energy and CO₂ emissions reductions in dwellings and it is easy to over-estimate the reductions achievable by retrofitting MVHR. Even with equipment specified to best practice standards the air permeability measured at 50 Pa must be reduced to less than 5 m³/m².h to reduce annual building energy. We expect to be able to compare these modelled predictions with measured data in a future paper.

That even competent installers of draughtproofing find it challenging to achieve low air permeability in existing dwellings, because of the high level of care and attention to detail required, is an important and worrying finding. In the case of the E.ON 2016 house it was necessary to rigorously seal the entire ground floor, as well as the various penetrations of the building envelope, in order to reduce the permeability to 5 m³/m².h. The disruption involved in this process is unlikely to be tolerated by the occupants, who additionally value the very features in their homes that make achieving airtightness difficult. Other approaches to energy efficiency may be easier to implement in existing dwellings than MVHR.

Towards Promoting Sustainable Construction In Egypt: A Life-cycle Cost Approach

Minass Assad, Ossama Hosny and Ahmed Elhakeem

School of Construction and Architecture Engineering, The American University In Cairo, New Cairo 11835, Egypt

E-mail: minas@aucegypt.edu ; ohosny@aucegypt.edu ; hakm73@yahoo.com

Abstract:

People spend most of their lives in buildings either homes, work places, education facilities or entertainment centers. Buildings represent a large economical investment and have huge effects on our lives and performance. With the presence of challenges such as: the rise in green house gases emissions, global warming, resource depletion..... etc., buildings design should have futuristic visions and innovative solutions to cope with such considerations. Design for sustainable/green buildings should be indispensable alternative in the construction industry. This paper introduces a framework for green buildings design in order to support planners to choose optimum customized building envelope design (orientation, walls, windows & roof) with least possible costs over the building lifetime. The proposed framework has unique focus on using sustainable approaches (material efficiency, indoor air quality, energy efficiency, passive solar design and natural illumination) to meet least life-cycle costs. A friendly prototype (Easy Design Integrated Tool- EDIT) is introduced based on proposed framework. It represents a comprehensive and easy application tool. (EDIT) is composed of five main modules: (1) user interface, (2) Interactive database, (3) systems builder, (4) systems assessment and (5) optimization engine. A case study is further implemented using the prototype (EDIT) and design results are discussed. Moreover, more analysis is developed as comparative analysis between green and traditional building designs. The analysis shows that green design exhibited life cycle savings of 16.3% and energy savings of 50% annually if compared to traditional design. Furthermore, simulation of all design systems alternatives is conducted to present a tradeoff comparison between initial and energy costs of different designs. Finally, the framework proves to be a credible, verified and validated. It can aid consultants, project managers and owner organizations at first stages of design to reach optimum building envelope systems design that ensure sustainability approaches and operation with least possible costs.

Keywords:

building thermal performance, design optimization, green buildings, life-cycle cost, sustainable design.

1 Introduction

Buildings' design is mostly selected based on standard construction techniques merely focusing on schedules and budgets only. Such techniques may overlook long term performance, environment impair...etc. According to the US Environmental Protection Agency, buildings contribute markedly to the environment degradation. Buildings alone use about 39% of total country's energy, consume 12% of the total water consumption and utilize 68% of total electricity utilization. Moreover, they emit 38 % of total carbon dioxide emissions (Green Buildings, 2010). According to that, sustainability techniques in building design should be employed without sacrificing costs or performance.

Three main aspects have contributed the most to motivate this research which are: (1) the current environmental challenges that the world is facing, (2) the lack of environmental awareness specifically in Egypt and (3) the presence of many limitations in buildings design research and tools. The first aspect is the environmental challenges as the rise in carbon emissions, global warming, scarcity of resources....etc which are great threat to the world (Intergovernmental Panel on Climate Change, 2007). Consequently, promoting the use of sustainable techniques in the construction industry would indeed serve as a constructive step to a better tomorrow for our society, country and world. The second aspect that motivated this research is that although most developed countries are aware of the globe environmental challenges and are adopting sustainability approaches, Egypt is still limping in such field. Till now, Egypt does not have an established buildings green rating system (Egyptian Green Building Council, 2011). Moreover, ignorance of green designs main principles has made engineers and investors fear their adoption and conceive it as waste of time and money (Shafik, 2009). The third aspect is the presence of limitations in available design tools/programs. Many design professional and investors criticize available design tools/programs for being complex and demanding since large amounts of information and detailed design are required for their operation which is usually not available at first design stages (Mckay, 2007).

This paper would be dedicated to promoting green/sustainable building design in Egypt by providing an easy comprehensive framework to be adopted. The research scope is shown in figure (1) to reach an optimum green building envelope design based on above mentioned considerations. The process is achieved through the formulation of a building optimum design that is based upon two levels. The first level is the building level which depicts the optimum building orientation from 8 different orientations. The second level is the systems level which depicts the best walls, roof and windows systems composition for each of the four facades of the building. The optimum design is based upon considerations as energy efficiency, thermal comfort, passive solar design, costs, daylighting, and user preferences.

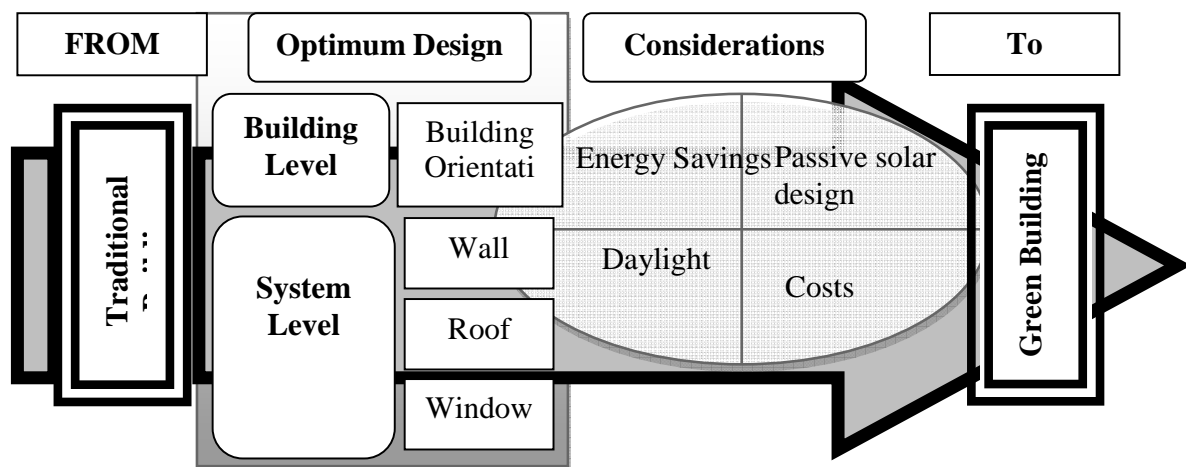

Figure1: Scope of Work

2 Literature Review

Researchers have been studying different green design parameters and their effect on the overall performance of buildings mainly energy savings or buildings life-cycle costs. Some of which have dedicated their work to study such effects on the cost of building systems. Some Researchers have been focusing on the whole life-cycle costs of buildings since buildings live tens of years (Fuller, 2007), while others just focused on certain aspects as energy savings (Abraham, 2003). Other researchers have been focusing on no-cost measures as building orientation to have less running costs (Winkler *et al.*, 2002). Some studies have been focusing on elements in the design as insulation and its contribution to the optimization of life-cycle costs (Abdullah *et al.*, 2008). Other designers have been employing optimization of multiple objectives as to reach optimum design (Nielsen and Svendsen, 2002). However, Most of them studied only one design parameter at a time and showed their performance on energy/life-cycle costs. Integration between different building systems is mostly ignored. Moreover, all their presented approaches/models need a high level of complexity. Also the integration of daylight analysis in green buildings has become an important strategy that has been overlooked in the research area (Nielsen and Svendsen, 2002). This paper research intends to build on the literature findings and attempts to avoid its limitations. It would offer a framework for an integrated green buildings design optimization. Parameters studied would be buildings envelope walls, windows, roof and orientation considering their integration effect. Green approaches would focus on indoor quality, thermal comfort and energy efficiency techniques. This framework is intended to address economic aspects and show savings as a tool to promote sustainability in construction management in Egypt. Furthermore, a generic model (EDIT) is discussed to be used by design professionals at conceptual design phases. Finally, a case study would be applied for discussing results and incurring risk assessment.

3 Research Methodology

The proposed framework to reach optimum green buildings' design is through the implementation of a model which its main modules are shown in figure (2). It consists mainly of 5 modules that interact together to reach the optimum green design.

3.1 Interactive Database

The first module is the “Interactive Dynamic Database”. This database is fed on 2 levels. The first level is more specific to the building or project under analysis. This information is related to the building studied as: the building geometry information as length (L), width (W), height of Floors, number of floors, area of window (%) and location of building. It also includes preferences in the analysis as preferred building interior temperature in summer and winter and the analysis Lifetime study (years). The second level is to set up the program. It mainly feeds 3 main groups. Group one is material related information including list of materials and their technical data as conductivity, U-value, shading coefficient, design parameters, lifetime. Group two is costs related information and it includes list of materials and their related costs (initial, maintenance, replacement) and energy costs.

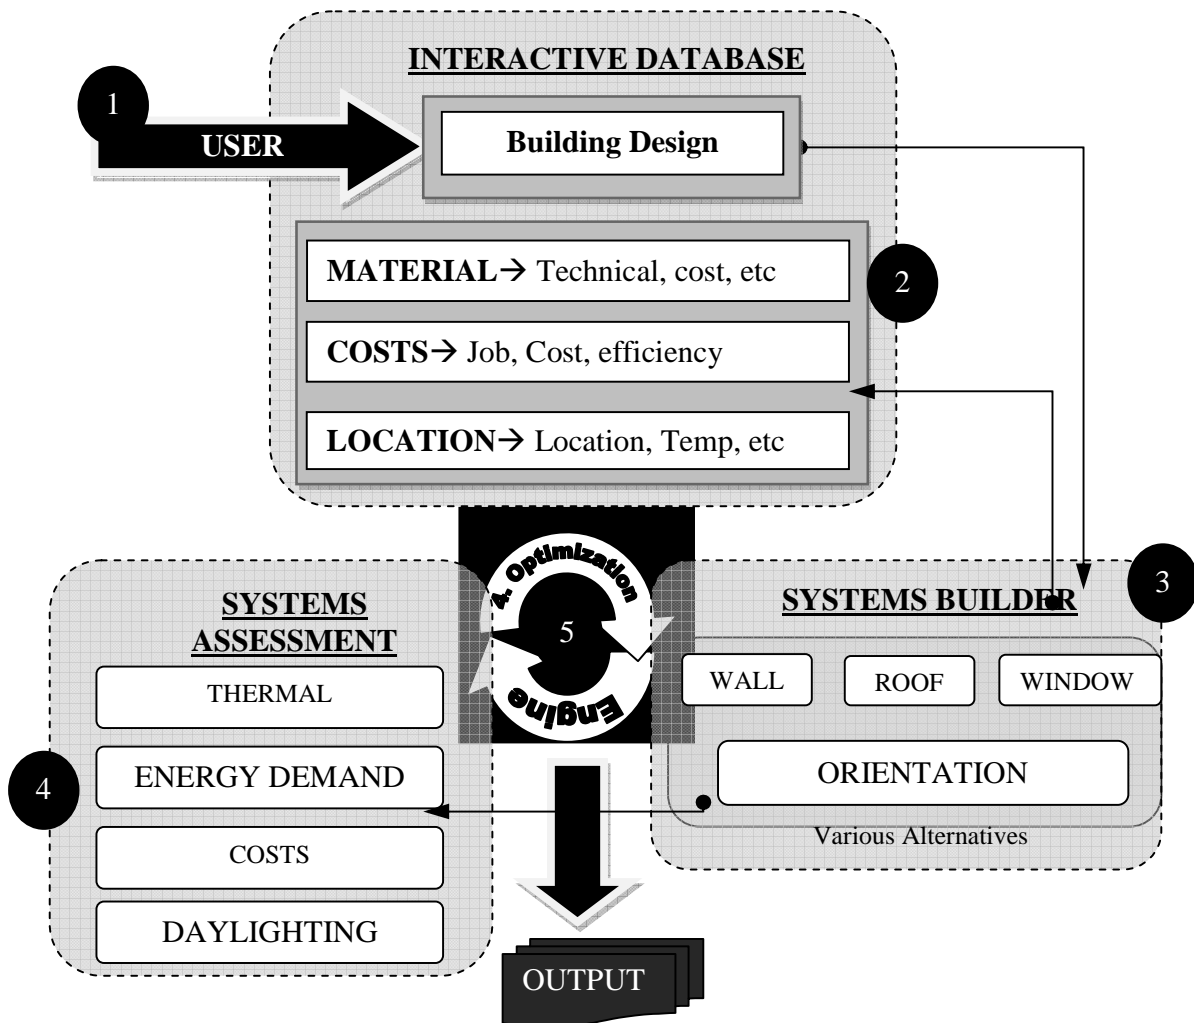

Figure 14: Framework Main Modules

Group three includes location related data as (1) weather related information as monthly average ambient temperature data, (2) orientation related data which also depends on location as solar heat gain factor and cooling load factors. This second level that contains the three groups is filled by model designer and it aids in feeding the system set up. To feed level two, integration of data should be processed depending on place of operation of the model. In this model, Group one and three sets of information were obtained from design books following the ASHRAE (McQuiston and Spitler, 1997). Group two was obtained from market and local contractors databases. (United Company, 2010) Group three was obtained from US department of energy (Weather Data, 2011). The first level is fed from user entry feeder and changes from one project to another. However, the second level needs frequent updating to be in phase with local and global changes.

3.2 Systems Builder

The Third module is the systems builder. This module builds different design systems in building envelope. Three main elements are considered in the envelope which are exterior walls, the roof and windows. The builder is mainly fed from the central dynamic database to produce different combination of systems under each element at different building's orientation. Different systems are formed of different alternatives to reach the optimum building orientation, walls system, roof system and windows system designs. The final optimum design is based upon certain green considerations. Considerations as indoor quality, material efficiency, energy efficiency and daylight measures are all included. Also cost is another consideration that is concerned. Finally, a daylighting index is also considered in the analysis. The considerations just mentioned above are fed to the system builder through module four which is the systems assessment.

3.3 Systems Assessment

The third module is the systems assessment. This system feeds the systems builder to reach the optimum building orientation and envelope design. Four main assessments are working in parallel: thermal, energy demand, costs and daylight.

3.3.1 Thermal Assessment

This first assessment calculates the amount of heat/cooling load needed to reach satisfactory thermal envelope condition. In this work, and with the absence of the residential building energy code for Egypt, the heating/cooling demands for residential buildings were calculated based upon the ASHRAE design book (McQuiston & Spitler, 1997). Heating/Cooling loads of buildings according to ASHRAE depend on three main assessments: conduction through building walls/roof, conduction through windows and solar radiation through glass. Heat gain/loss due to conduction through walls/roof (Watt/m^2) depends on U-value of the walls/Roof ($\text{Watt/m}^2 \text{ } ^\circ\text{C}$), the area of opaque walls/ Roof (m^2) and the different temperature between outdoor temperature and indoor preferred temperature ($^\circ\text{C}$). Heat gain through Windows (Watt/m^2) depends on U-value of the window glass ($\text{Watt/m}^2 \text{ } ^\circ\text{C}$), area of window (m^2) and different temperature between outdoor temperature and indoor temperature ($^\circ\text{C}$). Finally, solar heat gain (Watt/m^2) depends on the net glass area of windows (m^2), shading coefficient of window glass (unit less), solar heat gain factor for that orientation (watt/m^2) and cooling load factor (unit less).

3.3.2 ENERGY DEMAND

The second assessment is the energy demand. It relies on the amount of calculated heating/cooling loads needed to be offset received from the first assessment. Equation (1) is used to present the energy demand of any built system (Haines and Wilson, 1998).

$$\text{Energy Demand} = \frac{Q_{\text{Total of all systems}}}{\text{C.O.P}} \quad (1)$$

Where $Q_{\text{Total of all systems}}$ is the total amount of heat gain/loss in watts, C.O.P is the coefficient of performance of cooling/heating system.

3.3.3 Costs Assessment

Operation costs are mainly the electricity costs, Equation (2) is used to present the electricity costs per year (Haines and Wilson, 1998)

$$E = \text{Energy demand} \cdot h \cdot E_{\text{price}}$$

(2)

Where E is the calculated electric costs per given year (L.E /year), h is number of hours of operating cooling/heating system per year (hr), C.O.P is the coefficient of performance of cooling/Heating system depends on function needed and season of operation and E price is the price of 1kw.hr consumption of electricity (LE/kw.hr). E price is received from annual ministry of electricity and energy (Egyptian Electricity Holding Annual Report, 2011). After knowing all cost values and their repetition along the analysis period for all systems forming the building, all costs are discounted back resulting in an equivalent net present value for the whole building (NPV) (Sullivan, 2006). In this assessment, a market interest rate for each repeated cost is calculated from real interest rate and general inflation rate that can be obtained from Egyptian central agency for public mobilization and statistics (Price Indices, 2010) and then used in the NPV calculation (Sullivan, 2006).

3.3.4 Daylight Assessment

This assessment provides a set of daylighting indices for the four building façades. The natural illumination in (LUX) at a certain reference points is calculated from each façade orientation and daytime, view factor between reference position and window, Window to floor area ratio, the net glass area, and maintenance factor (Fikry, 2006). After the calculations of these daylight indices, one weighted sum is reflected to guide the internal design of the building.

3.4 Optimization Engine

With unique formulation and integration among the previous calculations, a building can be composed using arbitrary orientation and systems. For any arbitrary design total cost and daylight indices are automatically calculated opening the door for calculation. Due to the complexity of framework formulation non traditional optimization (GAs) is used.

4 Case study Application & Discussion

To implement the proposed framework a case study is introduced and implemented to (EDIT) model. (EDIT) model is composed of various spreadsheets. Many sheets were used as databases for material, labor/equipment, etc. Another sheet was developed to function as the system builder which is supported by data validation features of Ms Excel to select from available materials. In the same sheet technical data were matched and retrieved based on formed systems. Various calculators were developed after a proper decomposition for the equations needed for each calculator. Finally, a separate sheet was used as an interface which allows feeding the building information and preferences then facilitates optimization and results screening. For optimization EVOLVER 5.5 which is a GA based optimization solver for MS Excel was then used to optimize the design. Figure (3) shows a screenshot for the developed spreadsheet model. The considered

optimum design from the case study is envelope maximum thermal insulation of four facade walls and roof and no necessary insulation for windows.

4.1 Comparative Analysis

A numerical comparison is done to show the marked savings of the optimum green alternative by comparing it to its equivalent but of traditional design of least initial costs. The comparative results in (EDIT) shows that green alternative exhibits huge savings in the life-cycle costs and energy costs. A total life-cycle savings of 16.3% would be achieved if adopting the green design instead of the traditional one. Accordingly, the increase in initial costs for adopting the green design alternatives has resulted in approximately 5.4% increase. However, the energy savings have yielded 50% annual savings. Moreover discounted payback period between the green and traditional design is computed to be 3 years.

4.2 Sensitivity Analysis

It is worth reminding here that with the increase in population and demand, resources are becoming scarcer. One of such resources is energy. Thus, a sensitivity analysis is done to further understand the effect of electricity prices increase on life-cycle costs (LCC) and optimum design

4.2.1 Effect On Life-cycle Costs

The first assessed factor is percentage change in life-cycle costs due to electricity prices increase. A relationship has appeared between percent increase in electricity prices and percentage savings in life-cycle costs. If electricity costs would reach the double, the life-cycle costs savings would increase to 23.6 %.

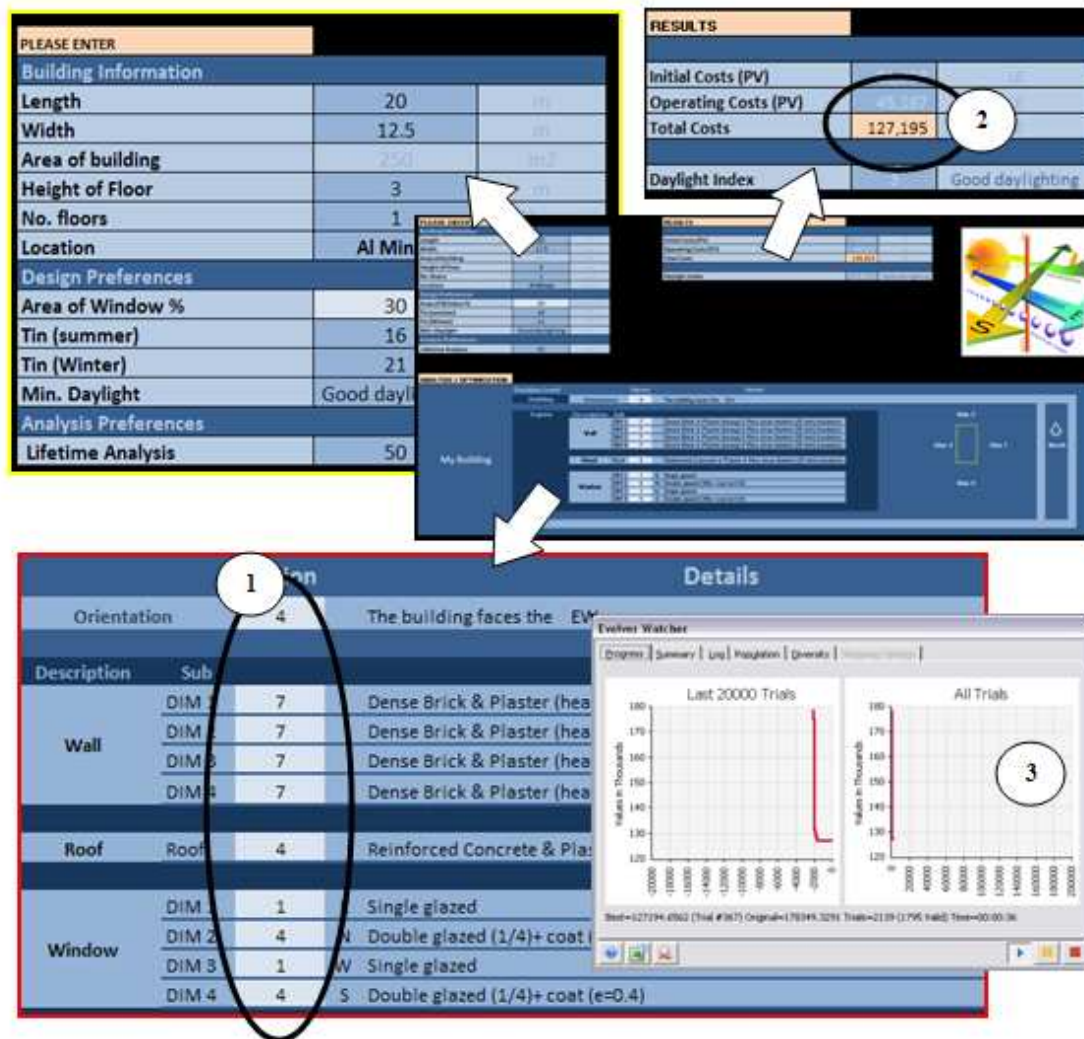

Figure 3:

1- Optimization Variable 2- Objective function 3- EVOLVER watcher

Implementation Spreadsheet Model

4.2.2 Effect on Optimum Design Scenario

Not only does the percentage increase in electricity prices changes the life-cycle costs, but it also changes the optimum design alternatives in each system. At 20% increase in electricity prices the optimum design would include different types of windows with more thermal insulation in east and south facades while still the south and north of no insulation. However, at 30 % increase in electricity costs, higher types of insulation alternatives are required for all the four windows facades.

4.3 Building Simulation

Another analysis is done to further study the green approach and its relationship to costs. Based on the current data in the construction elements database, simulation has been conducted to see the tradeoff between initial costs and energy costs

4.3.1 A Cost/Energy Tradeoff

Systems options were selected randomly based on discrete uniform distribution ranged from 1 to available options for each system. Two predictions were tracked, the building initial cost and the building energy costs (electricity cost/year). Nine thousand different design combinations were performed and all data were extracted. The relation between different design combinations initial and energy costs (electricity cost/year) for trade-off is plotted as shown in figure (4). The x-axis represents the energy costs of different building design combinations scenarios. The y-axis presents the total initial costs of each scenario. The graph represents the least energy consumption available scenarios (section 1 and 3). While the bottom half of the graph represents the least initial cost scenarios (section 3 and 4). Section 3 represents design combination scenarios with relative less initial and energy costs. Designers could further trace easily their optimum design. Also, comparative study can be easily made through such figure between different design scenarios alternatives.

Figure 4: The relationship between initial cost and energy costs

Finally the model was verified of being comprehensive, user friendly and of high quality. Two surveys were conducted about the model and distributed to eleven professionals for model validation and verification. The Professionals were four chairmen of large scale investment firms, two middle-large scale construction investment owners, three consultants and two architects. Professional experiences were chosen to range from 8 – 30 years in the field on construction in Egypt. According to those professionals, and after they applied the model to their own projects, it provided a comprehensive framework for green building design.

5 Conclusion and Further Research

With the world heading towards sustainability to face current and future challenges, green buildings in the construction industry has become an inevitable choice. Green building research has been lately prevalent however they include many limitations. Furthermore, green assessment tools were viewed by many design professionals as being complex and expensive. The main objective of this paper research is to promote sustainability in Egypt to serve a better tomorrow. This research aims at developing an integrated green building design framework with optimization features to provide an optimum green building envelope design with least available life-cycle costs. A case study was further implemented using the (EDIT) model. Comparative analysis between edit results and traditional design of least initial investments showed marked savings reaching 16.3% with a compounded payback period of only three years. Furthermore, simulation of all design systems alternatives has been conducted to provide easy tools for selecting optimum building design with relative less initial and energy costs. Finally, the (EDIT) model was verified and validated using surveys distributed to design professionals, consultants, developers, investors and owners.

This paper research opens the door to more research areas and considerations. If more sustainable parameters could be assessed as embodied energy, carbon footprint, recycling...etc., it would add greatly to the value of the work. It would raise environmental awareness along with the costs promotion. Moreover, if environmental benefits would be considered as non-tangible costs showing the effect of green construction on Egyptian people performance as their: productivity, internal health, mental integrity, performance, happiness...etc. Moreover, in this research buildings envelope components were only considered due to their most contributions to heat gain/loss that mostly affects building thermal and economic performance. However, other components as (interior walls, ceilings, doors, presence of equipment...etc.) can be further considered and show their effect on final results.

United States of America

Email: i-choudhury@tamu.edu

Abstract:

A Building Integrated Photovoltaic (BIPV) material has a great potential of being used as a source of renewable energy for buildings. The purpose of this study was to analyze the cost-effectiveness of BIPV roofing for residential buildings in the United States. A total number of 70 sites, 14 each from five climatic zones in the United States, were randomly selected for the study. A general linear model was used to find out the cost effectiveness of BIPV roof compared to asphalt shingle roof, using net present values of both the roof types. Net present value of asphalt roofing was done based on available database of material and labor costs in the cities selected. Net present value of BIPV roofing was done using a simulation model developed by National Renewable Energy Laboratory. A similar model was used to determine energy savings estimates for BIPV roof.

The results of the analysis indicate that the use of BIPV roofing is not currently cost-effective when compared to asphalt shingle roofing in residential buildings. However, the installation of BIPV roof tiles provide a significant saving in energy costs. The energy savings of a building using BIPV systems was found to be affected by annual heating degree days and location of the building.

Keywords:

Building Integrated Photovoltaic, cost effectiveness, energy savings, net present value, residential buildings

1 Introduction

1.1 Statement of the Problem

Building Integrated Photovoltaic (BIPV) is one of the most promising renewable energy technologies. It allows buildings to generate all or part of their energy needs using photovoltaic (PV) panels that are integral part of the structure. In BIPV systems, the PV array is part of the building's roof, wall, or windows. A PV array directly converts solar radiation to electrical energy. A residential PV system can be hooked up with utility grid, making it possible to export the excess energy to the utility company (Muhida *et al.*, 2009).

Even though BIPV technology has been in existence for over a decade, cost issues have slowed down wide-spread acceptance and installation of the systems. Cost-effectiveness of BIPV roof tiles, in comparison with asphalt roof shingles, for residential buildings has been analysed in this study. The primary objective of the study was to find out the economic viability of the use of BIPV roof tiles for residential buildings in the United States. Building Integrated Photovoltaic (BIPV) is one of the most promising renewable energy technologies. The primary objective of the study was to find out the economic viability of the use of BIPV roof tiles for residential buildings in the United States.

1.2 Hypothesis

1.2.1 Hypothesis 1

It was hypothesized that net present value of the roof of a residential building using BIPV roof tiles is significantly different that of the roof of a residential building using asphalt shingles.

1.2.2 Hypothesis 2

It was hypothesized that net energy savings of a residential building using BIPV roof tiles is affected by the climatic location of a building, and number of heating and cooling degree days of the location.

2 Literature Review

With an increase in worldwide energy consumption and consequent build-up of greenhouse gases, there has been a continuous pursuit for developing clean energy. The use of solar energy, in the form of PV cells, is recognized as an important approach to generate an environmentally friendly, sustainable, and clean energy to replace fossil fuels (Li and Lam, 2008).

Photovoltaic cells (PV) are made by joining P and N type semi-conductors. P types contain positive ions, while the N types contain negative ions. These ions produce an environment necessary for flow of electrical current within the cells. Current generated by the cells, is DC, which has to be converted to AC by using an inverter (Figure 1).

Figure 1. Residential BIPV Systems

PV cells were first used commercially in the late 1950s to power communication satellites (Cholakkal, 2006). Gradually, the practical application of the technology expanded to include building industry. The benefits of using PV energy compared to fossil fuel energy include (1) autonomy, (2) reliability, (3) sustainability, and (4) zero emission. The quantity of energy savings due to installation of BIPV systems, however, may be affected by the geographical location of the building.

PV cells can be woven into building components such as wall and roof, making them an integral part of the building. Building Integrated Photovoltaic (BIPV) systems activate the PV system very efficiently by utilizing PV cells as surface materials of buildings (Hoon *et al.*, 2011). The system assumes multi-faceted roles by replacing conventional exterior walls, roofs, windows, and shading devices.

BIPV systems for buildings can be either stand-alone or connected to grid. Grid-connected systems are advantageous in the sense that any surplus energy is exported to the utility grid, eliminating the need for on-site batteries. The owners are thus able to sell excess energy.

Apart from solar radiation, power production by BIPV is correlated with a number of other variables. They include (1) solar altitude, (2) solar azimuth, (3) outdoor dry-bulb temperature, (4) shading, (5) dirt accumulation on the surfaces, and (6) efficiency of the cells (Cholakkal, 2006). Solar altitude and azimuth, and outdoor dry-bulb temperatures vary according to geographical setting. It is, therefore, likely that quantity of energy savings due to installation of BIPV systems, may be affected by the climatic regions, and heating and cooling degree days of a location.

Despite some significant advantages of using PVs to produce energy, the manufacturing and installation costs of the systems were higher than that for conventional sources of energy in the past decade (Oliver and Jackson, 2000). A study done in the mid-2000s provides similar report related to cost-effectiveness of the technology (Cholakkal, 2006). Another study conducted by Muhida *et al.* (2009) also fails to offer any encouraging evidence in support of the BIPV systems as far as costs are concerned. The authors, however, conclude that “break event (sic) point for this system is still far from our wishes, but this system gives a contribution in reducing air pollution and promoting the clean energy (p. 698).”

Li and Lam (2008), however, report some positive economic aspects of using BIPV facades for 40-storey office building in Hong Kong. Their results indicate that when incorporated properly with daylight, the overall simple monetary payback for installation of BIPV systems would be 6 ½ years. This is remarkable considering the high first cost of the systems. The authors, of course, limit the findings only to commercial buildings.

There are some optimistic view points regarding cost-effectiveness of BIPV systems. Davis (2002), using what he calls an experience curve, reports that the price of PV cells decreased by 82 per cent over a period of one and half decades. Assuming a continuation of this trend, the author predicts that the production cost of BIPV-generated energy will be comparable to that of fossil fuel electricity by 2020.

The literature review provides an understanding of the basic principles, advantages, limitations, and economic aspects of BIPV systems. The cost of BIPV is reportedly on the decline. Based on the current cost of materials and installation of BIPV roof tiles, the cost-effectiveness of the system has been analysed in this study.

3 Research Methodology

3.1 Data Collection Procedure

Energy performance of BIPV roof tiles in different climatic locations of the United States was required to be ascertained for the study. This was done through simulation by using Solar Advisor Model (SAM), also known as System Advisor Model, developed by the National Renewable Energy Laboratory (US Department of Energy, 2011).

SAM is a performance and economic model designed to facilitate decision making for people involved in the renewable energy industry (Figure 2). The software makes performance predictions for grid-connected solar systems, small wind and geothermal power systems, and economic estimates for distributed energy and central generation projects. It calculates the cost of generating electricity based on information provided about a project's location, installation and operating costs, type of financing, applicable tax credits and incentives, and system specifications. SAM also calculates the value of saved energy from a BIPV system.

Figure2. Screenshot of BIPV analysis using SAM

All data related to BIPV roof tiles was collected by using SAM. The data included cost of BIPV roof tiles including their installation for all locations, operation and maintenance costs, cost of auxiliary devices such as inverters, and energy savings.

Cost of asphalt roof shingles for different locations in the United States was obtained from published sources (Waier *et al.*, 2010). The costs were adjusted for all different locations.

3.2 Location

Seventy locations were selected from the 5 different climatic zones of the United States, 35 each for buildings using BIPV roof tiles and asphalt roof shingles. The climatic zones are: (1) Zone 1 (Cool), (2) Zone 2 (Temperate), (3) Zone 3 (Moderately temperate), (4) Zone 4 (Hot and arid), and (5) Zone 5 (Hot and humid).

3.3 Prototype Residential Building

A simple prototype residential building was designed by the authors for the study (Figure 3). The roof area of the building was 1680 sq. ft. Data on different variables was collected for the same building, assumed to be constructed in all the selected locations. Data collection for buildings using BIPV roof tiles was done using SAM.

Annual incident energy striking a roof surface is a function of solar altitude and azimuth angles. SAM selected the part of the roof that would contribute to energy savings when BIPV roof tiles

were installed. Figure 4 shows the roof area selected by SAM for this purpose. Cost comparison was done based on only this part of the roof.

Figure 3. Roof plan of the prototype residential building

Figure 4. Roof plan of prototype building showing the location of BIPV roof tiles

3.4 Variables

Roof type (MATERIAL): It is the type of roof used for a residential building according to material used. This is a categorical variable with two levels, 1) BIPV and 2) ASPHALT.

Net Present Value (NPV): This is the net present value of the buildings using both BIPV roof tiles and asphalt roof shingles, assuming a life span of 25 years and discount rate of 10 percent. It was measured in US dollars. NPV was calculated using the cost of materials and installation of roof, energy savings due to installation of BIPV systems, and operations and maintenance cost of

the building during its life span. Since NPV takes into account all cost inflows and outflows of a project over its lifetime, it is considered as an ideal variable for analyzing cost-effectiveness of an investment. This variable was used as a proxy for cost of the prototype residential building at different locations.

Location (LOCATION): It is the climatic zone in which a residential building was located. This is also a categorical variable with five different levels, (1) ZONE 1, (2) ZONE 2, (3) ZONE 3, (4) ZONE 4, and (5) ZONE 5.

Energy savings (ENERGY): These are the net savings in electrical energy costs for a building using BIPV systems, during the first year of its operation. The variable was measured in US Dollars.

Annual Cooling Degree Days (CDD): A cooling degree day is a difference of 1°F between balance point temperature and average daily outdoor dry-bulb temperature of a location. When this difference is higher than the balance point temperature, it is one cooling degree day. The sum of this difference for a year is the annual cooling degree days for the location.

Annual Heating Degree Days (HDD): A heating degree day is also a difference of 1°F between balance point temperature and average daily outdoor dry-bulb temperature of a location. When this difference is lower than the balance point temperature, it is one heating degree day. The sum of this difference for a year is the annual heating degree days for the location.

4 Findings and Discussion

4.1 Hypothesis 1

5 Hypothesis 1 was tested using a General Linear Model available in SPSS statistical package. The following model was used for the analysis:

$$NPV = \beta_0 + \beta_1(MATERIAL) + \beta_2(LOCATION) + e \quad \text{Eqn. (1)}$$

Where NPV = net present value, MATERIAL = roof type in terms of material used, LOCATION = climatic location of the building, β_0 = intercept, β_1 and β_2 = regression coefficients, and e = error term.

Results of the analysis are shown in Table 1:

Table 1. Summary of statistical analysis using NPV as dependent variable

Variables		Intercept	Regression Coefficient	t-value	p-value
Intercept		-23155.98		-38.80	<0.0001
MATERIAL	ASPHALT		26214.65	31.06	<0.0001
	BIPV		0*		
LOCATION	ZONE 1		874.44	1.04	0.30
	ZONE 2		543.38	0.64	0.52
	ZONE 3		0*		
	ZONE 4		-1149.40	-1.36	0.18
	ZONE 5		-1745.60	-2.07	0.04
F = 540.38 p-value: <0.0001		Model R ² = 0.97		Adjusted R ² = 0.97	

* This parameter was automatically set to zero by SPSS.

The model, which is derived from empirical data, needs to be checked for its predictive efficacy. A widely used measure for checking the predictive efficacy of a model is its coefficient of determination, or R^2 value. Perfect relation is said to exist between the dependent and independent variables, if R^2 is 1 and no relationship exists between the dependent and independent variables, if R^2 is 0. Predictive efficacy of this particular model was found to be quite high with an R^2 of 0.97, and also an adjusted R^2 of the same value. This means that 97 percent of the variances in net present value (NPV) are explained by the variables included in the model.

The F-value of the model was found to be 540.38, which is statistically significant at less than the 0.0001 level. It indicates that the model as a whole accounts quite well for the behavior of the predictor variables.

The results indicate that net present value (NPV) has a statistically significant relationship with roof type (MATERIAL), at the level of significance of less than 0.0001. It means that BIPV roof tiles are not cost-effective compared to asphalt roof shingles used in residential buildings in the United States. This is despite the fact that the use of BIPV roof tiles generated considerable amount of energy (Table 2), resulting in a substantial saving in energy costs (Table 3).

Table 2. Annual energy output (in kWh/kW peak rating) from BIPV roof tiles installed in prototype residential buildings at 35 locations

Loc.	Annual Energy	Loc.	Annual Energy	Loc.	Annual Energy	Loc.	Annual Energy	Loc.	Annual Energy
1	4000	8	4100	15	3900	22	4800	29	4700
2	4500	9	3800	16	3700	23	4000	30	4200
3	3800	10	4800	17	3900	24	4100	31	4500
4	3500	11	4200	18	3900	25	5200	32	4200
5	3900	12	4000	19	3900	26	4700	33	4300
6	4300	13	4900	20	3800	27	4100	34	4900
7	4200	14	4900	21	5200	28	4200	35	4200

Table 3. Average annual energy savings (in US \$) for prototype residential building using BIPV roof tiles at 35 locations

Loc.	Annual average	Loc.	Annual average	Loc.	Annual average	Loc.	Annual average	Loc.	Annual average
1	939	8	1077	15	1010	22	1208	29	1199
2	1069	9	978	16	997	23	1062	30	1118
3	906	10	1190	17	911	24	1093	31	1146
4	890	11	1112	18	1040	25	1275	32	1102
5	1037	12	1049	19	1038	26	1164	33	1119
6	1069	13	1216	20	972	27	1076	34	1226
7	1005	14	1203	21	1290	28	1101	35	1100

None of location variables, except ZONE 5 (hot and humid region) were correlated with NPV of the buildings. It was found to be statistically significant at the level of 0.04.

5.1 Hypothesis 2

Hypothesis 2 was also tested using a General Linear Model using SPSS statistical package. This test was done using the data only from 35 locations where BIPV roof tiles were used for the residential buildings. The following model was used for the analysis:

$$\text{ENERGY} = \beta_0 + \beta_1(\text{LOCATION}) + \beta_2(\text{CDD}) + \beta_3(\text{HDD}) + e \quad \text{Eqn. (2)}$$

Where ENERGY = net energy savings cost, LOCATION = climatic location of the building, CDD = annual cooling degree days, HDD = annual heating degree days, β_0 = intercept, β_1 , β_2 , and β_3 = regression coefficients, and e = error term.

The results of the analysis are shown in Table 4.

Table 4. Summary of statistical analysis using ENERGY as dependent variable

Variables		Intercept	Regression Coefficient	t-value	p-value
Intercept		1423.61		13.61	<0.0001
CDD			0.011	0.66	0.52
HDD			-0.05	-3.23	0.003
LOCATION	ZONE 1		-72.26	-1.56	0.13
	ZONE 2		-199.71	-3.87	0.001
	ZONE 3		0*		
	ZONE 4		-141.44	-2.36	0.03
	ZONE 5		-222.01	-2.81	0.009
F = 6.39 p-value: <0.0001		Model R ² = 0.58		Adjusted R ² = 0.49	

* This parameter was automatically set to zero by SPSS.

F-value of this model was found to be 6.39, which is also statistically significant at less than the 0.0001 level. However, predictive efficacy of the model was not that high. Adjusted R² of the model was found to be 0.49. This means that 49 percent of the variances in energy savings (ENERGY) are explained by the variables included in the model.

The results indicate that net energy savings has a statistically significant relationship with almost all the climatic zones (LOCATION) except ZONE 1 (cool zone), at the level of significance of less than 0.05. It means that the savings in energy cost would be significantly different for buildings using BIPV roof tiles with respect to climatic regions in which they are located.

HDD (annual heating degree days) was also found to have a statistically significant on net energy savings, at less than the 0.05 level. The results show an inverse relationship exists between HDD and Energy, which means that higher the number of annual degree days, lower is the amount of energy cost savings. However, CDD was not found to have any statistically significant relationship with ENERGY.

6 Conclusion and Further Research

Use of BIPV systems in the building sector is receiving immense interest nowadays in order to make the buildings able to supply their own energy requirements. This study was conducted to find out the cost-effectiveness of BIPV roof tiles in residential buildings, compared to conventional asphalt roof shingles. A secondary objective of the study was to find out the factors of energy cost savings for residential buildings using PIV system.

Computer simulation, which is a non-invasive and powerful tool, was used for assessing the performance of BIPV systems. Particular software selected for the purpose was Solar Advisor Model (SAM) developed by the National Renewable Energy Laboratory. The findings of the study indicate the net present value of such buildings is significantly lower than that for buildings using asphalt roof shingles. In other words, at current costs of materials and installation, BIPV systems are not economically attractive for use in residential buildings in the United States. However, the results demonstrate that the use of BIPV roof tiles results in considerable saving in energy costs for the residential buildings. The net energy cost savings are correlated with all but one climatic region in which a building is located and the annual heating degree days of that location.

Despite this drawback, it would not probably be a good idea for the industry to give up on the technology altogether. It is energy-efficient, renewable, sustainable, and “green.” Apart from making the buildings autonomous, BIPV is one of the best sources of clean energy. Buildings, including production and transportation of materials, consume about 50 percent of energy (Wattkopf, 2007). A large portion of this percentage is used by residential buildings. Therefore, adoption of the technology by the building industry would help reduce environmental degradation to a considerable extent.

Like all other new innovations, the cost of BIPV is also continuously declining. Cost improvements are expected with the increase in cell efficiencies, reduction in the use of materials, and improvement in mass production techniques. It is expected to be eventually competitive with conventional energy in near future. Until the systems become economically attractive, financial incentives in the form of federal and state subsidies may be continued for dissemination of BIPV systems.

Only BIPV roof tiles have been analyzed in this research. Other BIPV components are also currently available. A study in Hong Kong (Li and Lam, 2008) was conducted to find out the cost effectiveness of BIPV façade for commercial buildings. The authors concluded that the payback period for such a system for a commercial building would be 6 ½ years. It would be interesting to conduct a similar study for residential buildings in the United States, using BIPV wall and window components.

Design of Reinforced Concrete Beams to ACI318-and-SBC304; and EC2 Codes

Ayed E. Alluqmani, David Haldane

Heriot-Watt University, Edinburgh-UK

Abstract:

Reinforced concrete beams are part of the structure so their design depends on the structural Code and its requirements. In this paper, two simply supported R.C. beams were designed in terms of flexural and shear strength design requirements when subjected to two asymmetric concentrated loadings, where one load is double the other one. Both beams had dimensions of 3500mm length, 200mm width, and 300mm height. The first beam (beam B1) was designed according to the combined of the structural requirements of American and Saudi Building Codes (ACI318-and-SBC304). While the second beam (beam B2) was designed according to the structural requirements of Eurocode (EC2). It was concluded from this paper that the ACI318 and SBC304 design approaches are safer than the EC2 design approach, while the EC2 design approach is more economic than the ACI318 and SBC304 design approaches.

Keywords:

R.C. Beams, ACI318-and-SBC304, EC2, R.C. Design, Flexural & Shear, Deflection & Crack

1 Introduction

Reinforced Concrete Beams are part of the structure so their design depends on the structural Code and its requirements. In this paper, the design method of reinforced concrete beams (narrow and wide beams) was outlined and compared in accordance with the structural American Building Code, ACI318, (ACI318, 2008) combined with the Saudi building Code, SBC304, (SBC304, 2007) requirements, and the structural Eurocode2, EC2, (EC2, 2004) requirements.

The objective of this paper is to study the theoretical design of 3500mm long simply supported reinforced concrete beams when subjected to asymmetric concentrated loadings, where one load is double the other one (140kN:70kN). The beam had a 200mm x 300mm cross sectional area. Two beams were designed in terms of flexural and shear strength design requirements and checked for serviceability (mid-span deflection and flexural crack width) check requirements. The first beam (beam B1) was designed according to the combined of the ACI318-and-SBC304 Code requirements (both Codes deal with the same design provisions). While the second beam (beam B2) was designed according to the EC2 Code requirement.

2 Literature Review

Reinforced concrete consists of two main construction materials that are used in the construction works, and were introduced in the first half of the nineteenth century; the first one is plain concrete, which will resist compressive stresses and the other is reinforcement bars to resist tensile stresses. Plain concrete is a mix of cement, coarse aggregate (gravel), fine aggregate (sand), water and admixtures, whereas the density of normal weight reinforced concrete is approximately 25 kN/m^3 (2500 kg/m^3); the gravel has gradation ranging from 6 to 25 mm particle size for building construction purposes

Reinforced concrete beams are common elements in more than 80% of the structures around the world, used as horizontal members transferring the load from the floor slab above them to the vertical members below them. The most common R.C. beams are in form of solid rectangular shape. The selections of their geometries are constrained by both structural and architectural requirements.

2.1 Reinforced Concrete (R.C.) Beams

The cross section shape of the beam, the main tensile reinforcing ratio, and shear reinforcement (stirrups) can have an effect on the beam design for flexure and shear capacity (Grant, 2003). In rectangular slender beams (either shallow and/or deep beams, or narrow and/or wide beams), the ultimate flexure and shear stresses increase when the member width to effective depth (b/d) ratio increases, (Figure 1). Also the increasing of beam width (b) is effect to increase both flexure and shear strengths of beams (Leonhardt and Walther, 1961; de Cossio, 1962; Alluqmani, 2010). Therefore, there is a benefit to use wide R.C. beam in construction industry which has a width larger its depth, where the rectangular R.C. beam which has a width (b) larger than its depth (d) and have obvious (b/d) ratio, is called wide reinforced concrete beam, and also is designed as conventional R.C. concrete beams. A wide beam must have a width to height (b/h) ratio exceeding 2.0, while slabs will typically have much larger ratios (Al.Dywany, 2010; Sherwood et al., 2006). Also, for wide beam, the shear span to effective depth (a/d) ratio is more than 1.0 (Teck FU, 2009). Wide members are frequently used as transfer elements where the total structural depth (h) must be kept to a minimum. Wide R.C. beams were used in buildings to reduce reinforcement congestion and floor heights for a required headroom. The beam width (b_w) in most of these cases is either equal or wider than that of the width of the supporting columns (b_s).

On the other hand, reinforced concrete beams are classified in general according to the geometry and shape of their cross-sections, as shown in Figure 1 and 2 (Al.Dywany, 2010), which bases on their dimensions, width (b), height (h), and length (L), where the structural designers classify the beams as following:

1. When $b \neq h$, the beam is rectangular slender beam
 - a) When $b < h$, the beam is drop, or narrow beam in the vertical position
 - I) When $h \leq 5b$, the beam is shallow beam
 - II) When $h > 5b$, the beam is deep beam
 - b) When $b > h$, the beam is wide beam in the horizontal position (usually, when $b \geq 2h$)
2. When $b = h$, the beam is square beam
3. When $b = h = \Phi$, the beam is circular beam

(Source: Sherwood et al., 2006).

Figure 2: Types of Concrete Beams According to the shape of their Cross Section
(Source: Al.Dywany, 2010).

2.2 Structural Design Codes

The standards of construction to which building work carried out in Saudi Arabia must adhere in terms of fulfilling legal obligations are set out by the Saudi Building Code, SBC. SBC Code accounts for a range of conditions including the social environment, climatic conditions, soil types and material properties (SBC304, 2007; Alluqmani, 2010). The structural Saudi building Code for concrete structures, SBC304, roots regarding the design concepts it embodies can be traced back to the American building Code for concrete structures, ACI318, (ACI318, 2002). However, although parallels can therefore be drawn between the two Codes in relation to methods of analysis and design procedures for example, significant disparities are evident due to the seasonal temperature changes in Saudi Arabia which impact on climatic conditions while soil classifications represent a further case for the relevant adjustments to be made. There is evidence that such adjustments have indeed been accounted for by the SBC304 Code (SBC304, 2007; Alluqmani, 2010). While within Europe, Eurocodes like the independent national Codes, finds a compelling template in the CEB Model Code (CEB-FIP, 1990). However, the presentation and choice of wording employed by the structural Eurocode for concrete structures, EC2, may be instrumental in making any otherwise obvious correlations with many national Codes (EC2, 2004). A relevant example can be seen in the manifestation of design provisions markedly akin to those of the British Standard, BS8110, Code (BS8110, 1997) and the CEB Model Code (CEB-FIP, 1990). As a set of technical Codes charged with overseeing both the analysis and design aspects of any impending venture within the field of civil engineering, the Eurocodes embody a fundamental element in presenting ten sections which form the foundations of the proper design and construction which should be closely followed by said projects. EC2 takes account of

stipulated standards for durability, serviceability, resistance and fire-resistance; elements which are accounted for by Structural Eurocodes (0), (1), (7) and (8), (EC2, 2004; Alluqmani, 2010).

As part of the EU agenda to facilitate harmonization within its borders, the Eurocodes displaced the national British Standards last year, although a degree of independence remained in the limited provisions which could be ruled on at a national level. A period of temporary disruption, evidence of which will invariably emerge in rising costs, is likely to ensue, although these should be tempered by the long-term benefits. The Eurocodes will become familiar terminology to new and forthcoming graduates of UK universities but will require intensive training to re-educate those designers currently employed within the civil engineering industry as to the recent changes (May, 2008).

3 Research Methodology

3.1 Design Methods (Ultimate Capacity and Serviceability)

The design of ultimate capacity (section capacity) to design both flexure and shear capacity according to the design provisions in **EC2** Code deals with the **Ultimate Limit State Design Approach**, while it deals with the **Ultimate Strength Design Approach** according to the design provisions in both **ACI318** and **SBC304** Codes. In the serviceability (mid-span deflection and flexural crack width) check, the three Codes deal with the **Serviceability Limit State Design Approach** (Alluqmani, 2010).

The main requirement for the design of section strength used in both **ACI318** and **ABC304** Codes is expressed as follows (McCormac, 2001):

Design Strength \geq Required Strength [Φ (Nominal Strength) \geq U]

$$\Phi P_n \geq P_u, \quad \Phi M_n \geq M_u, \quad \Phi V_n \geq V_u, \quad \Phi T_n \geq T_u$$

Where, P = Axial Load, M = Bending Moment, V = Shear Force,
 T = Torsion Moment, Φ = Reduction Strength Factor

All notations with (u), P_u , M_u , and V_u refer to the required strength values while the design strength values are denoted by (Φ *nominal strength), ΦP_n , ΦM_n and ΦV_n .

The main requirement for the design of section strength used in **EC2** Code is expressed as follows (Mosley et al., 2007):

$$\text{Design Strength} = \text{Characteristic Strength} / \text{Partial factor of safety} [R_d = R_k/\gamma_m]$$

The design resistance is equal to the characteristic resistance divided by the partial factor of safety for structural material.

3.2 Analysis and Design of Beam

The details of both beams that were used for analysis and design in this study is shown in Figure 3. The material properties for the ACI318 and SBC304 were a compressive strength of concrete (f_c) determined using a cylinder specimen of 30 N/mm^2 , the tensile yield strength of steel (f_y) is taken as 420 N/mm^2 for hot rolled or cold worked high yield steel, and 280 N/mm^2 for hot rolled mild steel strength (f_{ys}) for stirrups (10mm diameter). On the other hand, the material properties for the EC2 were a compressive strength of concrete (f_{ck}) determined using a cylinder specimen of 40 N/mm^2 , the tensile yield strength of steel (f_y) is taken as 500 N/mm^2 for hot rolled or cold worked high yield steel, and hot rolled mild steel, but normally EC2 uses 250 N/mm^2 for mild yield steel strength (f_{yv}) for stirrups (8mm diameter). The concrete cover (C_c) was taken as 25mm . The modulus of elasticity was $E_c = 24500 \text{ N/mm}^2$ for concrete and was $E_s = 200000 \text{ N/mm}^2$ for steel.

3.2.1 Beam Analysis

The beam that was analysed for this study is a simply supported beam. It carried two concentrated loads, of which one is double the other, and the total length of the beam is 3500 mm with a clear span is 2800 mm , as shown in Figure 3. The maximum shear force ($V_{\max.}$) is 123 kN and the maximum bending moment ($M_{\max.}$) is 86 kN.m .

Figure 3: S.F.D, B.M.D and Beam Details used in Analysis and Design
(Source: Alluqmani, 2010).

3.2.2 Beam Design

The differences of load factors and design factors between ACI318-and-SBC304, and EC2 Codes are illustrated in Table 1 and 2, respectively.

Table 1: Comparison of the load factors to ACI318-and-SBC304, and EC2 Codes
(Source: Alluqmani, 2010).

ACI318 and SBC304 Load Factors		EC2 Load Factors	
Dead Load, D.L (1.4 old)	1.20	Permanent Action, Gk	1.35
Live Load, L.L (1.7 old)	1.60	Variable Action, Qk	1.50
Wind Load, W.L	1.60	Wind Action, Wk	1.15

Table 2: Comparison of the design factors to ACI318-and-SBC304, and EC2 Codes
(Source: Alluqmani, 2010).

ACI318 and SBC304		EC2	
Strength Reduction Factor (Φ)		Material Partial Safety Factors ($1/\gamma_m$)	
Reinforcement	0.90	Reinforcement, ($1/\gamma_s$)	$1/1.15 = 0.87$
Flexural Concrete	0.90	Flexural Concrete, ($1/\gamma_c$)	$1/1.50 = 0.67$
Shear Concrete	0.75	Shear Concrete, ($1/\gamma_c$)	$1/1.50 = 0.67$

Figure 4 shows the comparison of stress-strain relationship for concrete that is assumed in the design process. The Elastic Modulus of Concrete (E_c) is the concrete stress divided by its strain, $E_c = \sigma/\epsilon$ (N/mm²) where, E_c = Elastic Modulus of Concrete, σ = Concrete stress, and ϵ = Concrete strain (Aitken, 2009). Also, it is obtained and taken as $4700\sqrt{f'_c} = 24,500$ N/mm² where the density of normal weight concrete is 2500 kg/m³ (25 kN/m²). While, Figure 5 shows the comparison of stress-strain relationship for steel that is assumed in the design process.

Figure 4: Stress-Strain Relationship of Concrete to ACI318-and-SBC304, and EC2 Codes
(Source: McCormac, 2001; Mosley et al., 2007).

Figure 5: Stress-Strain Relationship of Steel to ACI318-and-SBC304, and EC2 Codes
(Source: McCormac, 2001; Mosley et al., 2007).

4 Findings and Discussion

4.1 Finding of Beam Design Differences

The design differences refer to the diagram of the stress distributions (Figure 6), as shown below (McCormac, 2001; Mosley et al., 2007):

A. Ultimate (Specified) Concrete Strength Differences:

$$\text{ACI318-and-SBC-304: } f'_c = \Phi f_c = 0.90 * f_c = 0.90 * 30 = 27.00 \text{ N/mm}^2$$

$$\text{Also, } 0.85f'_c = 0.85\Phi f_c = 0.85 * 0.90 * f_c = 0.765f_c = 0.765 * (0.8 * f_{cu}) = 0.612f_{cu}$$

$$\text{EC2: } f_c = f_{ck}/\gamma_c = f_{ck}/1.50 = 0.67 f_{ck} = 0.67 * 40 = 26.80 \text{ N/mm}^2$$

$$\text{Also, } 0.85f_c = 0.85f_{ck}/\gamma_c = 0.85 * 0.67 * f_{ck} = 0.567f_{ck} = 0.567 * (0.8 * f_{cu}) = 0.454f_{cu}$$

B. Ultimate (Specified) Steel Strength Differences:

$$\text{ACI318-and-SBC304: } f_s = \Phi f_y = 0.90f_y = 0.90 * 420 = 378 \text{ N/mm}^2$$

$$\text{EC2: } f_y = f_{yk}/\gamma_s = f_{yk}/1.15 = 0.87f_{yk} = 0.87 * 500 = 435 \text{ N/mm}^2$$

In the three Codes, three types of stress distributions are used, triangular, parabolic (actual) and rectangular (equivalent) stress distributions, where the rectangular or equivalent stress-strain distribution is used in the design equations as shown in Figure (McCormac, 2001; Mosley et al.,

2007; Atiken, 2009; ACI318, 1984). However, the design equations are different, as shown below.

Figure 6: Equivalent Stresses and Strains Distributions on a Section Compared to both Codes
(Source: Mosley et al., 2007; ACI318, 1984).

C. Flexural Design Differences:

ACI318-and-SBC304: $K = M_n / f_c * b * d^2 = \mathbf{0.245}$, where, $M_n = M_u / 0.90 = \mathbf{95.6 \text{ kN.m}}$.

EC2: $K = M / f_{ck} * b * d^2 = \mathbf{0.163}$

Lever Arm

ACI318-and-SBC304: $jd = (2/3) * h = d - a/2 = \mathbf{200 \text{ mm}}$

EC2: $Z = d \{0.5 + \sqrt{[0.25 - (K/1.134)]}\} = \mathbf{212.3 \text{ mm}}$

Required Area of Tension Reinforcement

ACI318-and-SBC304: $A_{s, \text{req.}} = M_u * 10^6 / \Phi * f_y * jd = \mathbf{1138.9 \text{ mm}^2}$, use 4Φ20mm

EC2: $A_{s, \text{req.}} = M / (0.87 f_{yk} * Z) = \mathbf{932.3 \text{ mm}^2}$, use 3T20mm

The maximum spacing between the longitudinal tensile reinforcement in the three Codes should be not less than the bar diameter, maximum size of aggregate (plus 5 mm in EC2) or 20-25 mm (Mosley et al., 2007; ACI318, 1984). In this study, the compression reinforcement is used in the

design of the beam and it was assumed to be a quarter of main longitudinal reinforcement. Also, reasons for providing compression reinforcement are:

1. Reduced sustained load deflection,
2. Increased ductility, and
3. Change of failure mode from compression to tension (McCormac, 2001).

Required Area of Compression Reinforcement

ACI318-and-SBC304: $A_{s',req.} = 0.25 * 1138.9 \text{ mm}^2 = \mathbf{284.7 \text{ mm}^2}$, use 3Φ12mm

EC2: $A_{s',req.} = 0.25 * 932.3 \text{ mm}^2 = \mathbf{233.1 \text{ mm}^2}$, use 2T12mm

D. Shear Design Differences:

ACI318-and-SBC304: $V_c = 0.167 * \sqrt{f_c} * (b_w * d) = \mathbf{44.3 \text{ kN}}$, $V_s = A_v * f_{ys} * d / S_L = \mathbf{60.6 \text{ kN}}$,
 $V_n = V_c + V_s = \mathbf{104.9 \text{ kN}}$, $0.75 * V_n = \mathbf{78.7 \text{ kN}} < V_u = \mathbf{123 \text{ kN}}$, O.K.
 EC2: $V_{Rd,max.} = 0.124 * b * d * f_{ck} * [1 - (f_{ck}/250)] * 10^{-3} = \mathbf{214.2 \text{ kN}} > V_{Ed} = \mathbf{123 \text{ kN}}$, O.K.

$$A_{sw} = V_{Ed} * S_L / 0.78 * d * f_{yk} * \cot(\theta), \cot(45^\circ) = 1.0; \cot(22^\circ) = 2.50$$

Maximum Stirrup Legs Spacing Along the Beam Length (S_L)

ACI318-and-SBC304: $S_{L,max.} = 380(f_{ys}/f_s) - (2.5 * C_c) = \mathbf{191 \text{ mm}} \leq 300 * (f_{ys}/f_y) = 199 \text{ mm} < \mathbf{200 \text{ mm}}$ O.K.,
 But take $S_{L,max.} = \mathbf{185 \text{ mm}}$ to get 19 stirrups
 EC2: $S_{max.} = 0.75 * d = \mathbf{193 \text{ mm}} < \mathbf{600 \text{ mm}}$ O.K.,
 But take $S_{L,max.} = \mathbf{185 \text{ mm}}$ to get 19 stirrups

Minimum shear links

ACI318-and-SBC304: $A_{v,min.} = V_s * S_L / f_{ys} * d = \mathbf{157 \text{ mm}^2}$
 Use **19stirrupsØ10mm@ S_{L,max.} = 185mm** spacing centre to centre.

EC2: $A_{sw,min.} = V_{Ed} * 10^3 / 0.78 * d * f_{yk} * \cot(\theta) * S_L = 91 \text{ mm}^2$, $\cot(22^\circ) = 2.50$

Use 19stirrupsR8mm@ $S_{L,max.} = 185\text{mm}$ spacing centre to centre.

Maximum Stirrup Legs Spacing Across the Beam Width (S_w)

Two stirrup legs were used across both beam widths. The stirrup legs spacing across the beam width (S_w) was **140mm** for beam B1, and **142mm** for beam B2.

The details of section design for both beams (Beam B1 and B2) are demonstrated in Figure 7.

Figure 7: Design Details Compared for Both Beams

(Source: Alluqmani, 2010).

E. Deflection and Flexural Cracks Width Differences:

The three Codes use a Serviceability Limit State approach to calculate deflections and flexural crack widths but they are different in their calculations. Moreover, the three Codes are applied with the maximum flexural cracks width, which should not be greater than **0.40 mm** (ACI318, 2008; SBC, 2007; EC2, 204).

The **deflection** is calculated as follows:

ACI318-and-SBC304: $\delta = P.(L_o)^3 / 48E.I = \underline{5.81\text{mm}}$, where $I = b*h^3/12 = 450*10^6 \text{ mm}^4$.

EC2: $a = k.(L_o)^2.(1/r_b) = \underline{7.65\text{mm}}$, where, $k = 0.125 - [a^2/6] = 0.125 - [0.025^2/6] = 0.1249$, $(1/r_b) = M/E_c * I = 7.81*10^{-6}$

While the **flexural cracks width** is calculated as follows:

ACI318-and-SBC304: $z = [0.02f_s*(d_c*A)^{1/3}]/1000 = \mathbf{0.296mm} < \mathbf{0.40mm}$ O.K., where,

$f_s = 0.6f_y = \mathbf{252\ N/mm^2}$, $d_c = C_c + \emptyset_{str.} + \Phi_s/2 = \mathbf{45mm}$, $A = b*2d_c/ N_s = 200*90/4 = \mathbf{4500mm^2}$.

EC2: $w_{k} = S_{r,max.}*(\epsilon_{sm} - \epsilon_{cm}) = \mathbf{0.281mm} < \mathbf{0.40mm}$ O.K., where,

$S_{r,max.} = 3.4C_c + [(0.42*k_1*k_2*\Phi)]/\rho_{p,eff.} = (3.4*25) + \{(0.42*0.70*0.4*20)/[932.3/(200*257)]\}$

$= \mathbf{214.67mm}$, $\epsilon_{sm} - \epsilon_{cm} = 0.6*(f_y/E_s) = 0.6*(435/200000) = \mathbf{1.31*10^{-3}}$.

The calculations of mid-span deflection and maximum flexural crack width for both beams (Beam B1 and B2) are demonstrated in Table 3.

Table 3: Comparison of maximum Mid-Span Deflection and Flexural Cracks Width for both Beams (Resource: Alluqmani, 2010).

Beam Type	Deflection, mm	Cracks Width, mm
Beam B1	5.81	0.296
Beam B2	7.65	0.281

4.2 Discussion of Beam Design Differences

4.2.1 Flexure and Shear Reinforcement Differences

For the flexural and shear design, the design fundamentals of the three Codes are similar, but there are some differences in the design equations and notations. Beam B1 had a flexural reinforcement more than beam B2. While both beams had the same shear reinforcement, but, they differed in the stirrup diameter.

Generally, the EC2 design approach has a design which is economically better than the ACI318 and SBC304 design approaches; this refers to the design factors used in the three design approaches.

4.2.2 Deflection and Crack Width Differences

There are differences in the calculations of deflections and flexural crack width between the ACI318-and-SBC304, and EC2 design approaches.

Moreover, beam B1 had lower deflection and higher cracks width than beam B2, as shown in Table 3. These differences refer to the design of each beam where beam B1 had more tensile and compressive reinforcements than beam B2, based on the design factors used in both beams. Also, the deflections and crack width calculations depend on the properties of the structural materials (concrete and steel), and their design factors and strengths.

5 Conclusions

The ACI318 and SBC304 design approaches deal with design factors that are larger than the design factors used in the EC2 design approach. For that reason, both ACI318 and SBC304 approaches normally give more flexure and shear design than the EC2 approach. Also these give best strength and serviceable and then more safety in deflections and/or cracks width.

5.1 From this study, it was concluded that:

1. The ACI318 and SBC304 design approaches are safer than the EC2 design approach
2. The EC2 design approach is more economic than the ACI318 and SBC304 design approaches.

Construction Law

The Extent of Enforcement of The Penalty Clause on Public Sector Construction Contracts in South Africa

Maritz MJ and Tshikila S

Department of Construction Economics,
School of the Built Environment,
University of Pretoria, Pretoria, South Africa

Email: tinus.maritz@up.ac.za ; simphiwet@yahoo.co.uk

Abstract:

Background: A perception exists that public sector construction contracts in South Africa are generally completed late. The penalty clause is included in construction contracts to dissuade the contractor from completing the works later than the approved date. The extent of delays in the public sector, factors to be considered in determining the penalty/liquidated and ascertained damage (LAD) *quantum* and extent of enforcement of the penalty clause are unknown. The legal consequences of non-enforcement of the penalty/LAD clause, in light of the Municipal Finance Management Act 56 of 2003 (MFMA) and the Public Finance Management Act 1 of 1999 (PFMA) are also unknown.

Methodology: A survey, sample obtained through the convenience sampling technique, was conducted to investigate the extent of enforcement of the penalty clause, and matters connected thereto. Opinions of clients/employers, consultants and contractors involved in the implementation of public sector contracts in Gauteng province of South Africa were sourced through a questionnaire.

Findings: A need exists to develop a more scientific/sensible method to determine the penalty/LAD *quantum* in the public sector. There is a significant difference of opinion whether the penalty/LAD clause is generally enforced in delayed construction contracts implemented by the public sector in South Africa. There is a significant difference of opinion whether the type of works does influence the extent of enforcement of the penalty/LAD clause. Where the penalty/LAD clause is not enforced, it is mainly because clients are sympathetic to the contractor. Public sector clients are in violation of the PFMA and MFMA if they knowingly fail to recover penalties/LAD when these are due.

Research limitations: Using the convenience sampling technique means that the findings cannot be generalised, but provide a tentative overview of the situation. The research sample was only drawn from the province of Gauteng. The study only investigated the legal consequences of non-enforcement, and did not extend to general contractual/contract management consequences.

Practical implications: Public sector clients need to be awakened to the problems consequent upon the non-enforcement of the penalty/LAD clause, in regard to both contract administration and the legal consequences.

Keywords:

Construction contracts, liquidated and ascertained damages, penalties, public sector

1 Introduction

1.1 The penalty/LAD clause in construction contracts

Construction contracts normally make provision for a penalty clause (or sometimes liquidated damages/delay damages), which requires the contractor to reimburse the employer a certain pre-determined amount for the period the works remain incomplete after the lapse of the scheduled, and sometimes extended, time of completion. Damages for late completion of construction contracts are normally liquidated at the time of concluding the contract. This is because late completion of construction contracts is the most common breach normally suffered by employers in construction contracts (Eggleston, 2009). The main advantage of the penalty clause, compared to a claim for damages in construction contracts, is that the employer need not have suffered, or even alleged, any prejudice in order to be entitled to the penalties²²⁵.

The agreed time of delivery of the product by the contractor is an *essentialia* of the construction contract, as it must always be contained in the contract (Nagel, 2006). The inclusion of this completion date (or contract period) is a matter of economic importance, both to the employer and to the contractor (Uff, 2009). The penalty/LAD clause thus becomes an *incidentalia* of the contract as it seeks to exclude, limit or alter the *naturalia* (i.e. general damages) of the contract. The penalty/LAD provision is regulated, protected and enforceable in South Africa under the Conventional Penalties Act 15 of 1962 (CPA). It is worth emphasising that the CPA does not require one to differentiate between a penalty and LAD. This means that the clause is enforceable, whether it is a penalty or LAD. This is a major difference in the legal position in South Africa compared to some jurisdictions in the world, especially those whose common law is heavily influenced by the English common law, where a penalty provision is not enforceable (Eggleston).

1.2 Determination of the penalty/LAD amount

There is currently no sensible/scientific method used to determine the quantum of the penalty/LAD in the public sector. The significance of this is that section 3 of the CPA empowers the courts to reduce a penalty if it is found to be ‘out of proportion to the prejudice’ that is likely to be suffered by the employer/client. It is important to note that the CPA refers to prejudice and not the actual damages/losses. As observed by Binnington (2009), prejudice is a much wider term in law and which would embrace, consequently, far more issues than would simply be covered if the employer had to demonstrate the actual loss/damages it had suffered. In simple terms, it would be very difficult for a contractor to convince the court that the penalty is indeed out of proportion to the prejudice. This is because a contractor would find it very difficult to

²²⁵Steinberg v Lazard (2006) SCA 53 (RSA)

assess the extent of the employer's prejudice that flows from the breach. However, the need to determine the *quantum* of the penalty/LAD still exists. Brümmer (1998) found that penalties imposed by the Department of Public Works (DPW) are substantially lower than those of the private sector. This results in public sector clients being under-compensated for damages flowing from the breach of contract.

1.3 The enforcement of the penalty/LAD clause in the public sector

There is a general perception that public sector clients do not enforce the penalty clause. The extent of delays, if any, in construction contracts implemented by the public sector is also unknown. It is unknown whether the type of works, i.e. civil engineering or building works, affects the enforcement of the penalty clause. Brümmer found that building projects implemented by the DPW are generally completed later than the approved date. Brümmer also found that the main contributing factor for these delays was the poor work performance by contractors. The penalty/LAD clause, by its nature, is included in construction contracts in order to dissuade the contractor from completing the works late. The extent of enforcement of this clause in projects implemented by the public sector in South Africa is presently unknown. The reasons for the non-enforcement of the penalty clause are also unknown. The CPA provisions make it almost impossible for a contractor to convince the courts of that a penalty is disproportionate to the prejudice. Court challenges of a penalty/LAD clause cannot therefore be the reason for non-enforcement as was the case in Ghana (Tuuli *et al*, 2007). In fact, there is only one reported court judgment in South Africa where a contractor successfully challenged the enforcement of a penalty clause²²⁶. Even in that case, the penalty was reduced because the court found that the prejudice suffered by the employer (Umkhanyakude District Municipality) was not caused by Afriscan Construction (the contractor) alone, but by other parties as well, whom the contractor had no control over. The court then apportioned the penalty accordingly.

1.4 Legal consequences of non-enforcement of the penalty/LAD clause

Two legislations were promulgated in South Africa to regulate, amongst others, the management of public funds by state organs; namely; the national, provincial and local government as well as other state-owned entities. The Public Finance Management Act 1 of 1999 (PFMA) regulates the management of public finances at national and provincial spheres of government as well as state-owned entities whereas the Municipal Finance Management Act 56 of 2003 (MFMA) regulates the management of public funds at local government level. The two legislations place a duty on public sector organisations to recover monies due to these organisations and prevent wasteful, fruitless or inefficient expenditure. The two legislations also regulate the contract management practices of state organisations. At face value, it appears that the clients' failure to recover penalties/LAD due to them could be a violation of the provisions of these legislations and could thus amount to financial misconduct.

²²⁶ Afriscan Construction (Pty) Ltd v Umkhanyakude District Municipality & another [2005] JOL 14365 (D)

1.5 The purpose of the study

The purpose of the study can be summarised as follows:

To investigate the extent of enforcement of the penalty/LAD clause in construction contracts implemented by the public sector in South Africa, as well as matters connected thereto;

To investigate whether the type of works, i.e. civil engineering or building works, has influence on the enforcement of the penalty/LAD clause by public sectors clients;

To investigate the reasons for non-enforcement where instances of non-enforcement of the penalty/LAD clause are prevalent; and

To investigate whether the non-enforcement of the penalty/LAD clause by public sector clients amounts to the violation of the MFMA and PFMA.

2 Research methodology

A descriptive quantitative study was undertaken to solve the research problem. Research data were collected by means of a questionnaire survey that targeted construction industry professionals in the Gauteng province of South Africa.

2.1 Research questionnaire design

The research questionnaire contained seven sections (Section 1 to 7), with each section generally designed to obtain information that relates to each sub-problem. The questionnaire was designed such that open-ended questions were avoided. A combination of rating scales and checklist were used, depending on the type of question. The five-point Likert (rating) scale enabled the measurement of the intensity of the respondent's feelings about a statement, while the checklist was used to test which of the possible answers apply to the respondent. A few control questions were incorporated to detect instances where the respondents attempted to provide "socially acceptable" responses (Leedy & Ormrod, 2010).

The University of Pretoria's Department of Statistics evaluated the questionnaire and checked for compatibility with the proposed statistical analysis methods. The questionnaire was then tested in a pilot study, with five respondents, to highlight any ambiguities and other potential problems. Minor adjustments were then made based on the comments and problems highlighted during the pilot study.

The same questionnaire was used for clients, consultants and contractors. However, those sections that did not apply to one category were highlighted in the instructions to prospective respondents.

Respondents were asked to answer questions relating to projects where formal Construction Industry Development Board (CIDB) endorsed standard conditions of contract were used.

2.2 Research population and sampling

The research population consisted of public sector clients, consultants and contractors operating in the Gauteng province of South Africa. The three categories also represent the main role-players in the implementation of construction contracts in South Africa. The study was restricted to those individuals that have access to email, as the questionnaire was distributed only by email. The population groups were obtained as follows:

Clients – project/contract managers of national, provincial and local government departments that implement construction contracts in Gauteng. This group also included municipalities and state-owned entities in Gauteng;

Consultants – active members of the South African Institution of Civil Engineering (SAICE) and the South African Institute of Architects (SAIA); and

Contractors – contractors registered with the CIDB that are based in Gauteng. The minimum CIDB grade for contractors was 7. Only contractors registered in the civil engineering (CE) and general building (GB) category of works were included.

The convenience sampling technique was used to select a representative sample for each category. The sample size was made up of 20 client bodies, 450 consultants and 80 contractors.

2.3 Data collection

The data was collected over a period of two months. The questionnaire was distributed by email to all the prospective respondents. However, respondents were at liberty to return the completed questionnaire by email or fax. To address issues of internal validity of the study, the researcher's hypotheses were not disclosed to the respondents (Leedy & Ormrod).

2.4 Data analysis

A total of sixty-two responses were received, fifteen from clients, thirty-six from consultants and eleven from contractors. The statistical analysis of the data was performed with assistance from the Department of Statistics and the results analysed by the researcher. Figure 1 illustrates the breakdown of the responses as a percentage of the total responses.

Figure 1: Distribution of responses received

3 RESULTS AND DISCUSSION

3.1 General particulars

Section 1 of the questionnaire sought general particulars of the respondents. Responses were received from a range of professions as shown in Figure 2. The majority of respondents have a civil engineering background, followed by those with an architectural, quantity surveying and project management background. The four professions generally cover most of the civil engineering and building works implemented by the public sector in South Africa. The category of “other” was made up of electrical and mechanical engineers. These two professions mostly work under a principal agent, whose background is normally one of the four professions mentioned earlier. This therefore indicates that the nature of responses will be representative of the majority of work in the public sector.

Figure 2: Professional affiliation of respondents

The above indication is confirmed by the distribution of the type of work that the respondents mostly handle, as shown in Figure 3.

Figure 3: Breakdown of type of works handled by respondents

The respondents were also asked to indicate their levels of experience in the industry. The idea was to assess the quality of the responses as they relate mainly to professional experience in the construction industry. As shown in Figure 4, the responsibility of administering construction contracts in this instance is placed on relatively well-experienced. The average working experience of the respondents is in the bracket of 10 to 20 years. The indicated experience of consultants is not surprising, as these professionals were drawn from SAICE and SAIA. Both institutions require experience in their respective professions, a minimum of five years, for an individual to be admitted as a member. Clients appear to be, generally, the least experienced of the respondents.

Figure 4: Breakdown of type of works handled by respondents

3.2 Penalties/LAD in construction contracts

The respondents were asked if they are familiar with the CPA. This legislation regulates the enforcement of the penalty/LAD clause in South Africa. Contract administrators are therefore expected to be at least familiar with the provisions of such legislation. How else do they ascertain and enforce a contractual provision whose regulatory provisions they are not familiar with?

However, as shown in Figure 5 a significant proportion of clients (60%) and consultants (50%) are unfamiliar with this Act. Interestingly, most of the contractors indicated that they are familiar with the Act.

Figure 5: I am familiar with the Conventional Penalties Act

Respondents were asked if they believe that penalty/LAD provisions are still relevant in construction contracts. Binnington (2009) believes that other forms of encouraging the contractors to finish on time, instead of dissuading them from completing the works later than the approved completion date, should instead be used.

Figure 6: Penalty/LAD provisions are a useful tool to dissuade the contractor

The majority of respondents believe that penalty provisions are still relevant and are a useful tool to dissuade the contractor from completing the works later than the approved date. But are they enforced in the public sector? An enquiry was made as to whether the enforcement of the penalty clause increases the rate of production (work performance) in construction contracts. Brümmer found that building projects implemented by the DPW are generally completed late due to poor work performance by the contractor. The effectiveness of the penalty clause in speeding up the rate of production in construction contracts was, however, not investigated in that study. The respondents are in agreement that the enforcement of the penalty clause (or the threat thereof) increases the rate of production in a construction site.

Figure 7: The enforcement of the penalty clause increases the rate of production

Respondents were asked whether there should be a relationship between the penalty/LAD and the likely prejudice, as provided for in the CPA.

Figure 8: There should be a relationship between the penalty/LAD likely prejudice

There is agreement that there should be a relationship between the penalty and prejudice likely to be suffered by the client. Surprisingly, all clients agree that there should be a relationship between the two. Whether they actually ensure that such a relationship exists would be interesting to see. It is also worth mentioning that a number of respondents are not familiar with the CPA as indicated earlier, but merely provided their opinion as to the relationship between the penalty and prejudice.

Respondents were asked to rank what they consider as the most significant factors in the determination of the penalty/LAD *quantum*. The statistical mean of each category was then determined and the average of all the factors is as shown in Table 1.

Table 1: Ranking of significant factors in determining the *quantum* of the penalty/LAD amount

Description	Clients	Consultants	Contractors	Average of all respondents	Rankings
Potential loss of use of facility	1.27	1.22	1.55	1.35	1
Construction supervision costs	2.87	2.78	2.8	2.82	2
Interest rate on capital invested	3.27	3.06	2.55	2.96	3
A factor of the envisaged contract value	2.93	3.14	3.7	3.26	4
Professional fees	3.87	4.31	4.64	4.27	5

The most significant factor is the potential loss of use of the facility. Unfortunately, Loots (1995) showed that the potential loss of use of the facility is very difficult to assess in public sector projects at tendering stage. By their nature, public sector infrastructure is not primarily income generating. In the circumstances, the second highest ranked factor, the construction supervision costs, can easily be determined and used. Interestingly, the most common factor that is currently used in South Africa's public sector is the estimated construction cost (Brümmer).

Figure 9: There is a need for a sensible/scientific method to determine penalty/LAD

Eighty percent (80%) of the respondents are in agreement that a scientific or more sensible method should be developed to determine the penalty/LAD *quantum*. Such a method could even make provision for all the significant factors in the determination of the penalty/LAD *quantum*, depending on the nature of the works.

3.3 The extent of enforcement of the penalty clause in the public sector

Respondents were asked to indicate the percentage of their public sector contracts that are completed later than the approved date. Figure 10 shows that 94% of the respondents' contracts are completed late. In fact, about 20% of the respondents indicated that more than half of their contracts are completed late. Figure 11 also shows that public sector construction contracts are generally completed late. This is a very high proportion by any standards. But is the penalty

clause enforced, considering that the respondents agreed that the penalty/LAD clause is useful?

Figure 10: What percentage of your public sector contracts are completed late?

Figure 11: Public sector construction contracts are generally completed late

In the light of the above finding that public sector contracts are generally completed late, and as shown in Figure 12, a high proportion of respondents indicated that they sometimes do not enforce the penalty clause, despite their belief that, firstly, the public sector contracts are generally completed late, and secondly, the penalty is an effective tool to dissuade the contractor from completing late. The responses, however, do not show a general practice of non-enforcement of the penalty clause, as the results show a significant difference of opinion in this regard.

Figure 12: I always enforce the penalty/LAD clause whenever applicable

When asked to state their reasons for non-enforcement, the respondents highlighted the following reasons.

Figure 13: Reasons for non-enforcement of penalty/LAD clause

The prevailing reason for non-enforcement is that clients are sympathetic to the contractor (24%). This is the still the case despite what appears to be a legal duty on public sector clients to recover penalties as provided for in the MFMA and PFMA. It is, however, not surprising that there are fewer instances of non-enforcement due to a successful legal challenge by a contractor of the enforcement of the penalty clause. In South Africa, there is only one reported court judgment where this has happened. It is, however, possible that other challenges may have been

mounted at arbitration proceedings, which, by their nature are private matters and thus not reported. Whether section 3 of the CPA also empowers the arbitrator to reduce the penalty is not clear (Binnington).

3.4 The influence of the type of works on enforcement of the penalty clause

The next enquiry was whether the type of works does affect the extent of enforcement of the penalty clause. The idea was to ascertain whether in civil engineering, for example, the penalty clause tends to be enforced compared to building contracts, or vice versa. Building contracts mostly use the Joint Building Contracts Committee (JBCC) standard contracts, whereas civil engineering contracts tend to use the General Conditions of Contract for Civil Engineering Works (GCC), FIDIC conditions of contract or the NEC suite of contracts. This would therefore

give an indication of, amongst others, the strictness of the different contracts. Figure 14 shows that there was a significant difference in opinion as to whether the type of works affects the extent of enforcement of the penalty clause.

\

Figure 14: The type of works affects the enforcement of the penalty clause

3.5 Legal consequences of non-enforcement of penalty clause in the public sector

The respondents were also asked questions about the possible legal consequences of non-enforcement of the penalty clause, as provided for in the MFMA and PFMA. Respondents were first asked if they are familiar with the specific provisions of these legislations, especially public sector clients.

The respondents generally indicated that they are familiar with these provisions. The next question was whether a public entity is in violation of the two laws if they knowingly fail to recover penalties due to that public entity. There is general agreement that a public sector client is in violation of the MFMA or PFMA (whichever is applicable to the entity) if they fail to recover penalties in their contracts.

Figure 15: I am familiar with the responsibilities of accounting officers in terms of the MFMA and PFMA

Figure 16: Knowingly failing to recover penalties/LAD by a public entity is a violation of the MFMA and PFMA

In the light of the above finding, it is surprising and disturbing that there are some public sector clients that still do not generally enforce the penalty clause.

4 CONCLUSION

The CPA is a very unique piece of legislation in that it provides the legal framework upon which penalties and LAD provisions can be formulated and enforced. The legislation makes it clear that contractors are not going to find much sympathy in our courts should they attempt to escape contractual provisions that they have willingly accepted. This should serve as a major encouragement for employers/clients to enforce the penalty/LAD provisions. Unfortunately, it was found that very few clients are familiar with the legislation. It then follows that they are less likely to know about the protection they enjoy from that legislation. Interestingly, a significantly higher proportion of contractors knew about the existence of the legislation, significantly more so than the consultants and clients. It may well be that contractors regularly check the CPA provisions in order to escape the enforcement of the penalty clause.

There is general agreement amongst the parties that the enforcement of the penalty clause increases the rate of production on site, which, anyway is what clients want. The clients' sympathy is therefore not a good enough reason not to enforce the penalty/LAD clause, let alone the consequent violation of the MFMA and PFMA, as found in this study.

The study also showed that there is a need to develop a method to determine the penalty/LAD *quantum*, and that there should be a relationship between the penalty/LAD and the likely prejudice. A sensible method that takes into account the main factors should be developed. In South Africa, public sector clients tend to consider a factor of the contract value. This appears to be an “easy-way-out” approach because the value of the contract sometimes bears no relationship to the prejudice that the client will later suffer. Even worse, previous research showed that the penalty clause has been found not to even fully compensate the public sector clients in the event of late completion.

The benefits of the proper assessment and enforcement of penalty/LAD provisions cannot be over-emphasised. This study highlighted the problems associated with the non-enforcement of the penalty clause. Tighter measures need to be implemented by the public sector to ensure that the penalty/LAD clause is indeed enforced. There is a clear positive relationship between enforcement and rate of production. Many other secondary problems surface if public sector construction contracts are not completed on time. These include poor expenditures on government infrastructure grants, reduction in the pace of infrastructure development, deterioration of existing infrastructure as well as other consequences that a developing country like South Africa cannot afford.

The Management of Construction Agreements in South Africa

Michelle de Oliveira¹

North West University, Potchefstroom Campus,
South Africa

Email: 22294996@nwu.ac.za

Abstract:

The management of construction agreements within the built environment of South Africa is not properly regulated. The effect of this may be seen in instances such as the poor quality of housing being built for the Rural Development Project, corruption as well as the dismal dispute resolution currently taking place. The Construction Industry Development Board, created in terms of the Construction Industry Development Board Act of 2000, is mandated in terms of section 4(f) to regulate the actions as well as procedures of parties engaged in construction contracts. Unlike the United Kingdom where the Housing Grants Construction and Regeneration Act 1996 deals with the shortcomings similar to those experienced by the South African Construction Industry; such as dispute resolution and the role of the parties. South Africa introduced the General Conditions of Contract for Construction Works (GCC). The latest edition is GCC 2010. It attempts to provide for guidelines to the construction industry. The GCC 2010 provides for dispute resolution, penalties, risk, the role of the relevant parties, to name but a few. However, there is no obligation on the parties to follow the said guidelines. It is uncertain whether the said measures adequately address the shortcomings experienced in the construction industry and up to now the GCC has not contributed towards the improvement of the situation. The aim of the paper is to critically analyse the GCC 2010 as a tool to manage construction agreements, with particular reference to dispute resolution, and to recommend improvements.

Keywords:

adjudication, construction contract, contract management, dispute resolution, South Africa

1 Introduction

The construction industry in any country, especially in South Africa, plays an 'indispensable role' in the economy thus having a direct impact on the public. It is essential that the industry improves on its effectiveness and efficiency which will inevitably enhance the environmental outcomes, safety, health, productivity as well as quantity and value for money to society' (Construction Industry Development Board Act 38 of 2000). South Africa unfortunately does not have legislation that would greatly assist in the achieving of the aforementioned goals. The

United Kingdom, whom may be seen as one of the forerunners in this regard, is a good example of where legislation positively aids in the regulating of the industry. The English implemented the Housing Grants, Construction and Regeneration Act 1996 (HGRC) which stipulates the *essentialia* of a construction contract and provides for adjudication; amongst others. The justification that has been provided for this intervention by the State is that adjudication will contribute to a more balanced cashflow in construction projects which will enhance the overall performance of the construction industry (Ndekugri & Russell, 2006). This viewpoint has been taken globally as may be evidenced by other states introducing same into their legislation such as New Zealand for example. South Africa is, unfortunately, not one of the States to take such initiative.

The South African construction industry had, for many years, numerous so called ‘in house contracts’ used by the various parties. However, when new entrants were prevented from competing freely for contracts as well as the lack of discipline that resulted from the confusion of conditions of contract, the South African government decided to take action (SAICE (2010) Management Guide). The Government of South Africa enacted the Construction Industry Development Board Act 38 of 2000 to ensure that leadership and ‘active promotion of best practice’ in the industry takes place. The regulatory body established in terms thereof is the Construction Industry Development Board, commonly known as the CIDB. In light hereof the CIDB has clearly defined powers and objectives such as to improve on delivery management, to establish as well as promote uniform and ethical standards which regulate the actions of those engaged in construction contracts. The CIDB Act goes on further to compel the CIDB to establish a register of contractors so as to facilitate the procurement process, albeit Public or Private Sector, as well as to obtain data so as to be utilised as a monitoring tool in the regulation of contractors’ behaviour. There are 3 main fields of engineering in the construction industry namely mechanical, electrical and civil engineering and as such different contracts are therefore utilised in each field.

Focus shall be placed on how the improvement of contract management may aid in the reduction of disputes between the parties. Focus shall also be placed on the GCC 2010 specifically as to whether the dispute resolution method currently used prescribed therein is effective in resolving disputes arising in terms of the aforementioned contract.

2 The Various Construction Agreements used in South Africa

The Green Paper on Creating an Enabling Environment for Reconstruction, Growth and Development in the Construction Industry highlighted the fact that simplification of the contract documents, streamlining of surety arrangements and those of payment procedures were required. There are currently four standard forms of construction contracts currently being utilised in the South African construction industry namely FIDIC (French acronym for International Federation of Consulting Engineers), The Joint Building Contracts Committee (JBCC Series 2000), The General Conditions of Contract for Construction Works 2010 (GCC 2010) as well as The New Engineering Contract (NEC3). The GCC 2010, NEC3 as well as FIDIC are the standard forms of contract that may be used in all types of engineering and construction projects. The JBCC 2000 is confined to building works. For purposes of this paper focus shall be placed on the GCC 2010. The South African Institute of Civil Engineers (SAICE),

developed a Management Guide to the General Conditions of Contract 2010, as a guideline to assist with the interpretation of the GCC 2010; of which said interpretation should not be seen as a legal interpretation thereof. According to Willie Claassen, the compiler, the aim of the guide is to promote efficient and effective management of construction contracts to which the GCC 2010 applies. He believes that the GCC 2010 will have an influence in the reduction of claims and disputes arising in terms of the GCC 2010 as it improves

...management techniques in construction projects. It does not only set out legal terms of rights and obligations, but concentrates much more on the conditions for good project management.

(Claassen, W. GCC 2010)

2.1 The GCC 2010

The GCC 2004 was replaced by the GCC 2010. Certain amendments and/or improvements may be seen in the fact that the contract has gone from a 58 clause contract to a contract that comprises of 10 clauses, being the GCC 2010; which is in line with the objectives of the CIDB. The aforementioned contract has been revised to the extent that the parties' responsibilities have allegedly been clearly defined. However, the contract has still remained very subjective in that the engineer has retained all his/her rights and/or powers and the contractor has not been afforded rights and/or protection therein.

2.2 The NEC3

This family of contracts was originally conceived in the mid-eighties after the London Institution of Civil Engineers approved a recommendation provided to it by its Legal Affairs Committee. The reason for the recommendation was in lieu of the fact that the engineering and construction professionals advising that there was an urgent need to approach contracts with a different view; specifically to do that more in line with the approach to project management. The Engineering and Construction Contract (ECC) incorporates three important components namely:

- i) Conditions of contract;
- ii) Risk management; and
- iii) Process / project management

One of the main characteristics of the ECC is that it encourages teamwork as well as elaboration so as to increase the opportunities for partnering to occur. Partnering, according to the CIDB, is defined as

...working together in a way that suits particular partners and which suits the particular project or service being procured. There is no stable template for partnering. There are, however, key elements which determine whether or not a particular procurement process is likely to yield the benefits from a true partnership. The key words associated with partnering are: co-operation; openness; shared standards; common objectives; respect for each partner's motivation; and trust. Partnering is about sharing costs, risks and rewards.

So in effect this particular construction contract establishes a “real time” contract management process (CIDB Best Practice Guideline C2) requiring cross organisational boundaries.

3 Research Methodology

The author made use of legal research methods. Firstly a literature review was done by referring to various literature comprising of books, journal articles, legislation and case law. It is important to note that there are no updated South African sources relating to the GCC 2010 with the exception of an article or two written by an engineer. After having read through the limited sources available so as to ascertain the theoretical background of what dispute resolution methods are used in the South Africa Construction Industry in particular those specified in the GCC 2010 a comparative study between South African and England was then attended. The purpose was to compare the difference in the manner within which adjudication as a dispute resolution method is applied. Each source was analysed so as to assist in arriving to the conclusion that efficient contract management is imperative and that the South African dispute resolution procedure prescribed in the GCC 2010 is inadequate and should be regulated.

4 Management of the Contract

One of the most underestimated areas in an organisation is contract management. According to the UK Office of Government Commerce, contract management is a process enabling the contractual parties involved to meet their obligations so as to deliver the objectives arising in terms of the contract by proactively managing the contract so as to anticipate future needs and react to situations that may arise (OGC 2002 Contract Management Guidelines). It further entails building a ‘good working relationship’ between the parties that shall, hopefully, continue throughout the life of the contract.

Many organisations are moving towards a more ‘informal’ method of contract management where constructive relationships between the parties are built as well as a more rewarding method called financial incentive management is used as opposed to the formal traditional manner of contract management, where contractor’s were usually at ‘arm’s length’. The contract forms the foundation for the contractual relationship. In light hereof it is essential to have the right contract in order for efficient contract management to take place. Aspects such as quality of service required, allocation of risk, communication methods and/or procedures and resolution of disputes, to name but a few, should be included in the contract. The GCC 2010 is said to make adequate provisions for the aforementioned factors. It is further said to have improved on the defining of the parties’ roles as well as the dispute resolution process.

One of the most common problems experienced by organisations with numerous contracts in place is that they are plagued with paper intensive contracting; of which said contracts are stored electronically and/or manually (De Oliveira, M. 2011). Therefore, emphasis must be placed on developing a sound contract management infrastructure by addressing the essential area of contract lifestyle management. Presently many organisations are establishing contract management departments so as to ensure that proper and effective contract management takes place (Barret, G. & Cummins, T 2011).

Modern day trends of contract management have two main characteristics in common namely to clearly define the parties' roles so as to achieve the agreed main objectives in terms of the contract and to encourage a symbiotic relationship between all the parties involved (Fisher S, *et al* 2009). It may be said that contract management involves the easing and resolving of tensions so as to build a relationship which benefits all the parties involved resulting in a win/win relationship. According to Siyabonga Mbanjwa there seems to be a general consensus that 'contractual arrangements' may improve in achieving the objectives of the client as well as have a huge influence on the failure and/or success of a construction project. (Mbanjwa, S. 2003). Therefore, effective contract management results in the monitoring of delivery performance of the appointed contractors as well as in saving opportunities (De Oliveira, M. 2011).

According to SAICE, the management of the GCC 2010 is the responsibility of the Employer's Engineer and of the Contractor's site agent (SAICE (2010) Management Guide). The SAICE Management guide goes on further to stipulate that a substantial amount of power is bestowed on the Engineer in the GCC 2010. The guide goes on further to stipulate that the

"...time-trusted arrangement of contract management by the Site Agent/Engineer ensures that timeous and well-considered decisions are made, and encourages the parties to take all possible steps to avoid conflict;"

illustrating the point that the resolution of conflicts can be planned for.

5 Dispute Resolution

There are various alternative methods other than litigation to resolve disputes between the parties namely arbitration, mediation, negotiation, adjudication, refereeing. All of these methods have certain characteristics in common in that they are supposed to be cost effective, expedient and presided over by a neutral third party.

The prescribed dispute resolution method in the GCC 2010 may be seen as a three-pronged process: first the parties attempt to resolve it amicably amongst themselves failing which a notice of dispute must be furnished to the engineer. Secondly the engineer is to make a ruling and should either party be dissatisfied with the ruling the matter may be referred to adjudication which forms the third leg. Adjudication is seen as a combination of mediation and arbitration where a third party adjudicates on the matter and provides a ruling which may be final should the parties agree thereto. According to SAICE, the GCC 2010 has been updated so as to include the 'latest thinking of dispute resolution' (SAICE (2010) Management Guide). However, is it really the latest thinking? If one has reference to the English construction industry for example, it will be noted that the English have been utilising adjudication for many years and have gone so far as to include the procedure as well as the contents of the contract in legislation, of which said legislation is specific to the construction industry and deals with the day to day obstacles encountered. Northern Ireland, as small as it may seem, has also developed a Construction Act. South Africa is extremely behind in that there is nothing regulating contracts let alone the construction industry.

Furthermore the whole point of alternative dispute resolution is the fact that it is said to be more expedient and cost effective. If one refers to the procedure found in the GCC 2010 it is

somewhat lengthy as well as costly. The reason for this is that each stage involved in the adjudication process is 28 days meaning that a dispute is resolved within 90 to 100 days; resulting in the process being substantially drawn out. The impression created by the GCC 2010 is that 28 days is a reasonable time. Whilst this may allow for the individual tasked with resolving the dispute to assess the matters, the nature of the construction industry does not always allow for such a prolonged period. Clause 10 deals with claims and disputes. Clause 10.1 specifically deals with the contractor's claim relating to the extension of time and/or additional payment/compensation. The contractor has to submit a written claim to the engineer within 28 days of the occurrence substantiating the reasons for the extension and/or variation. The engineer is to furnish the employer as well as contractor with his written recommendations within 28 days of receipt of the written notice. If the contractor disagrees with something in the contract he is to first attempt to resolve it with the engineer amicably; should this not resolve itself then the aggrieved party must furnish the other with a dispute notice (clause 10.3 GCC 2010). If one had to monitor the process more efficiently the amount of disputes that take place would in all likelihood reduce. Adjudication in South Africa is becoming costly as well as lengthy and the way within which it is applied in South Africa it defeats the purpose of alternative dispute resolution.

As a result more non-traditional mechanisms have been introduced to resolve disputes; namely:

Private Judging in which participants hire a third party judge to make a decision

Neutral Expert fact-finding in which a third party with specialised knowledge makes a recommendation

Mini-trial in which legal summaries of the participants' position are presented to a jury comprising of principals of the affected parties.

(Civil Engineer)

6 Conclusion and Recommendations

Conflicts between parties are inevitable. That having been said, it is blatantly obvious that South Africa needs to do something so as to circumvent the ever increase of disputes arising between the parties due to various factors; the one being poor contract management as well as to make the chosen method of alternative dispute resolution more efficient. The English took the initiative and regulated their construction industry which can be seen as successful. South Africa should learn from its English counterparts and attend to the regulating of its construction industry. Greater emphasis must be placed on regulating the construction industry, focusing primarily on the contract used as well as the dispute resolution method, so as to allow for efficient contract as well as project management to take place and for the occurrence of disputes to reduce alternatively to be dealt with expeditiously.

Abstract:

Sustainable building is becoming ever-more popular in the U.S. and around the world. Historically, sustainable building practices have ebbed and flowed with the cost of energy. As energy prices go up, a heightened awareness is placed on sustainable building; as energy prices go down, the industry goes back to its traditional building practices with sustainability being a “footnote”. In the past few years a number of associations have championed the topic and are making headway towards governmental requirements and keeping the topic in front of the general public so as to not let the strides made in the past few years subside as they have in the past.

As sustainable building practices become more mainstream, owners are requesting, and sometimes requiring, that the design and construction contracts contain some language that addresses the sustainability goals of the owner. This can be as simple as achieving a certain rating by one of the accrediting (or certifying) associations or as nebulous as reaching some level of efficiency.

However, what happens if the goals set by the owner are not achieved? Who carries the liability if this is the case? In addition, the certification process is normally carried through at the completion of the project (if a new construction) and there is typically little to no follow-up required to ascertain or verify that the expected efficiencies are indeed being met.

This study will examine the potential damages that may exist if sustainability objectives fall short of their expectations. In addition, the authors will look at model design and construction contracts and the potential damage theories that have evolved over the years. While conclusions of law can only be made by the courts, we will discuss how sustainable contract language fits within the traditional theories of damage and how it does not. Where conclusions of law have been reached by the courts we will include them with our discussion. The goal of this paper is to uncover the different measures of damage that are utilized when a construction team fails to meet its sustainability goals.

Keywords:

consequential damages, contracts, green, law, sustainability

1 Introduction/Background

When owners begin planning a project, they typically assemble a program to guide their project's design; this can include numerous criteria such as a space needs assessment, preliminary layout, and their desired level of finish. Increasingly in this early planning stage owners identify the sustainability objectives that they want their building to achieve. These objectives may include performance goals such as energy efficiency measures, and/or it may include a third party certification such as LEED®, BREEAM, Green Star or Green Globes. Whatever their sustainability objective may be, if the owner wants to make it more than just an aspiration, they will include it within their contract documents. The question then becomes who is responsible if the contracting parties do not meet this objective and what measure of damages should be assessed.

In the United States a number of organizations provide the construction industry with model contract documents. These organizations tend to be forward thinking and are relatively quick to adapt their model contract documents to procedural and technological changes within the industry. The three primary organizations which provide this service include: 1) American Institute of Architects ("AIA"); 2) ConsensusDOCS®; and 3) Design Build Institute of America ("DBIA"). Their model contract documents can be adopted by a project team and easily tailored to a specific job. Many owners and developers use these documents or at least consult them when forming their agreements between project team members. Since these model documents are regularly consulted when forming agreements they carry a great deal of influence within the industry as it relates to how contracts are drafted and the general rights of the contracting parties.

Each of these three organizations has produced a separate guide to enable a project team to successfully navigate and achieve a certain sustainability goal. There are some commonalities between each organization's framework for assigning responsibilities and resolving issues, but there are also some notable differences.

The AIA contribution to sustainable construction is AIA D503. This document is not so much a model contract as it is a guide with selected contract language intended to modify their other agreements. The hallmarks of the guide's suggestions include the project team developing sustainability objectives; then creating sustainability measures and a plan to achieve the sustainability objectives. The guide goes on to suggest specific language it would incorporate with its governing agreement between the architect and owner and it suggests the same for the governing agreement between the contractor and owner. An excerpt from the AIA D503 follows:

The Owner and Architect acknowledge that LEED® Certification is awarded by the Green Building Certification Institute (GBCI), an independent third party organization, and is dependent on factors beyond the Architect's control, such as the Owner's use and operation of the Project; the Work provided by the Contractor or the work or services provided by the Owner's other contractors or consultants; or interpretation of credit requirements by GBCI. Accordingly, the Architect does not warrant or guarantee that the Project will be granted LEED® Certification by the GBCI.

For both the architect and contractor the guide suggests that these parties should include a mutual waiver of consequential damages which is intended to insulate them from consequential damages flowing from their failure to meet a sustainability objective. As illustrated below, D503 goes on to provide another layer of protection from potential liability flowing from a failure to meet sustainability objectives. This liability limitation is a type of umbrella coverage for the contracting parties.

Neither the Contractor, Contractor's consultants, nor their agents or employees shall be jointly, severally or individually liable to the Owner in excess of _____ (\$_____), for any failure to perform a Sustainable Measure or failure of the Project to achieve the Sustainable Objective, including breach of contract or negligence not amounting to a willful or intentional wrong.

Add the following Section 15.1.6.3 to A201–2007:

The ConsensusDOCS[®] organization addresses sustainability through an addendum to ConsensusDOCS[®] 310. As with the AIA publication this addendum is not intended to operate on its own; but is to be used to modify the underlying governing agreements. ConsensusDOCS[®] sustainability goals are referred to as green measures. These “measures” are similar to what was defined as sustainability objectives in the AIA documents. The ConsensusDOCS[®] make the “green measures” the general responsibility of the project team with ultimate responsibility resting with the Green Building Facilitator (“GBF”). The documents allow the drafter to select the “GBF” from among the architect, engineers, contractor, or presumably a third party such as a sustainability consultant.

The ConsensusDOCS[®] 310 does a great job of allowing the contract drafter to specifically define the “green measures” as either a certain “elected green status” meaning a third party certification (LEED, BREEAM, Green Star, Green Globes) and/or some performance based criteria such as a specific energy efficiency level.

After the ConsensusDOCS[®] 310 sets the table for the project team in regards to goals, roles and responsibilities, it discusses liability. In a fashion similar to its other provisions, it allows the drafters to elect how best to transfer the risks between the project team members. It first tries to define any damages resulting from a failure to meet green measures as consequential damages and then subjecting those damages to applicable mutual waivers of consequential damages in the governing contract. See language below from section 8.2

Owner's loss of income or profit or inability to realize potential reductions in operating, maintenance or other related costs, tax or other similar benefits or credits, marketing opportunities and other similar opportunities or benefits, resulting from a failure to attain the Elected Green Status or intended benefits to the environment, shall be deemed consequential damages subject to any applicable waiver of consequential damages in a Governing Contract unless specifically excluded from such a waiver in the Governing Contract.

Under the ConsensusDOCS[®] addendum the default protection applies to all parties except the GBF. See language below.

Unless otherwise expressly provided in a Governing Contract, no Project Participant other than GBF shall be liable or responsible for the failure of the Elected Green Measures to achieve the Elected Green Status or intended benefits to the environment or natural resources. This Paragraph 8.3 does not relieve any Project Participant from any obligation to perform or provide Elected Green Measures as required by its Governing Contract.

The DBIA is another organization that provides model contract documents to the construction industry. Like the AIA and ConsensusDOCS®, the DBIA has created an addendum to be used as a guide with its governing document. The DBIA addendum has a provision for defining sustainable project goals but allows the drafters to select from three remedies in the event that any of these goals are not met. The three remedies are: 1) the parties can agree to a waiver of claims, such that the failure to achieve the desired sustainable goals (including the targeted level of certification) will not be deemed a breach of contract and will nullify any such claims; 2) the parties have the option to agree that the failure to meet the sustainable goals for the project will cause the Design-Builder to be liable for liquidated damages in an amount agreed to at contract formation; and 3) the parties can agree that the Design-Builder has an obligation to cure any failure to achieve the desired sustainable goals through the addition, replacement or correction of materials, configurations, systems or equipment in order to obtain the third party certification or certain sustainable performance measure (Kelley & Vornehm, 2009).

2 Contract Damages

A brief review of the common law of contract damages would be instructive as to potential liabilities facing the project participants who are responsible for the success or failure of a sustainability objective. These are the typical contract damages that a breaching party may be liable for if they fail to achieve a sustainability goal. As stated in American Jurisprudence 2nd, under a general allegation of damages resulting from a breach of contract, a plaintiff may recover those damages that naturally and necessarily result from the alleged breach. The plaintiff must show a compensable injury resulting from the alleged breach.²²⁷ In a breach-of-contract action, a plaintiff may recover the amount of damages necessary to place him in the same position he would have occupied had the breach not occurred. This is measured by a combination of 1) direct damages; 2) consequential damages; and 3) any offset for not having to perform.²²⁸

Direct (or “general”) damages are those that are the natural and necessary result of the wrongful act or omission. Said another way, direct damages are those which are traceable to, and the probable and necessary result of, the injury. They are the direct, natural, logical, and necessary consequences of the injury, or usually flow from the breach.²²⁹

Consequential (or “special”) damages, denotes damages that arise from the special circumstances of the case, which, if properly plead, may be added to the direct damages which the law presumes or implies from the mere invasion of the plaintiff's rights. Consequential damages are

²²⁷ 22 Am. Jur. 2d Damages § 624

²²⁸ Restatement 2nd of Contracts, §347 “Measure of Damages in General”

²²⁹ 22 Am. Jur. 2d Damages § 38

the natural, but not the necessary, result of an injury. Thus, they are not implied by law, and while they need not be the necessary and usual result of the wrong, they must be a proximate result thereof.²³⁰ This rule is generally derived from the holding in *Hadley vs. Baxendale*.²³¹

In a more modern interpretation of this rule within the construction environment, the Supreme Court of Virginia weighed in on the difference between direct and consequential damages and found for the plaintiff on the issue of whether extended interest cost related to a job being finished late was a direct damage.²³² In that same case the Supreme Court of Virginia found that some interest expenses were consequential damages.

Many owners choose to pursue a green building for a variety of reasons, including the fact that they wish to capitalize on higher rents and asset value that are perceived to derive from third-party green building certification, as well as potentially lucrative financial incentives offered by state and local governments. If the party responsible for attaining third-party certification fails to accomplish the goal as required by contract, the damages that flow from that breach may be deemed both direct and consequential damages (Prum & Del Percio, 2010). Because of the green building arena's novelty, courts have yet to set a precedent as to whether the damages should be considered direct or consequential (Prum & Del Percio, 2010).

3 Case Law

Looking at reported case law to establish the legal precedent can help to conclusively answer some of the questions that have been referred to above. Unfortunately reported cases on this aspect of green building law are sparse to non-existent. In the course of researching the current legal precedent some initial pleadings and factual background were uncovered on a state trial court case which is related to this subject and provides some insight. This case is *Shaw Development vs. Southern Builders*. The following set of facts concerning the lawsuit were uncovered by a blogger working at gbNYC magazine. The lawsuit in question relates to the construction of a \$7.5 million condominium complex in coastal Maryland. From what can be gleaned from the initial pleadings it appears that the specifications included a stated goal for the project to achieve a LEED silver certification issued by the United States Green Building Council. The owner's interest in this LEED silver rating was not purely altruistic, as there were state tax incentives related to new buildings achieving LEED certification. In this case the state of Maryland was offering tax credits up to 8% of the total project costs for projects which achieved a LEED certification. These tax credits were not specifically mentioned or claimed in the contract but the LEED certification was clearly stated in the specifications as a sustainability objective. As it turns out the performance of the project team delayed the receipt of LEED certification which subsequently disqualified the owner from receiving the tax credits; and, as such, the owner pursued a cause of action against the builder based partially on these lost tax credits (Del Percio, 2008).

Unfortunately for legal commentators and academics this case never proceeded to trial and was settled out of court. But the facts of the case illustrate the types of disputes and claims that will

²³⁰ 22 Am. Jur. 2d Damages § 40

²³¹ *Hadley v. Baxendale* (1854) 156 ER 145.

²³² *Roanoke Hospital Association v. Doyle & Russell, Incorporated* (1975) 215 Va. 796

undoubtedly be seen in the future related to one party's failure to achieve a sustainability objective.

4 Discussion

Without established legal precedent some common threads may be uncovered from the model contract documents and the basics of contract law. It appears that contract drafters are managing their risk using a few common strategies. It is also clear that owners are looking for ways to ensure their project participants meet the sustainability measures.

The first and most desired risk avoidance strategy for contractors and architects is a waiver of consequential damages. Most of the sustainability guides attempt to define damages related to the failure to meet a sustainability objective to be consequential, then further rely on the waiver of consequential damages in the governing contract to absolve the parties of liability. It appears that some of the damages flowing from a failure to meet a sustainability objective would be considered a consequential damage (i.e. decreased rents, decreased asset value, failure to acquire lucrative financial incentives offered by state and local governments). However, the danger with relying on this risk avoidance strategy is that some damages related to a failure to achieve a sustainability goal may be deemed direct damages; and the line is often blurred between direct damages and consequential damages. The AIA has added some umbrella coverage for possible direct damages by adding a limitation of liability provision in addition to the mutual waiver of consequential damages.

The other type of risk sharing strategy which has been mentioned in both the ConsensusDOCS and DBIA addendums is some sort of liquidated damage provision relating to a parties failure to meet a sustainability objective. This may be the most reasonable and balanced approach considering the interest of all parties. It is clear that in these cases, harm has been done to the owner if a sustainability objective is not met. And it further stands to reason that if the owner feels strongly about the sustainability objective that message can be conveyed clearly by putting a price tag on it in the form of a liquidated damage clause when the contract is initially negotiated. This type of liquidated damage would be subjected to the typical legal challenges and as such would have to be drafted carefully. According to the Restatement 2nd of Contracts, "Damages for breach by either party may be liquidated in the agreement but only at an amount that is reasonable in the light of the anticipated or actual loss caused by the breach and the difficulties of proof or loss. A term fixing unreasonably large liquidated damages is unenforceable on grounds of public policy as a penalty."²³³

With respect to liquidated damages, no court to date has interpreted a green building-related liquidated damages provision. As a result, a provision that imposes liquidated damages on a party for failing to earn the owner's desired level of LEED certification may in some jurisdictions, be deemed a penalty and thus an unenforceable condition of the contract (Prum & Del Percio, 2010).

A third option addressing this issue has recently been brewing in Washington D.C. In 2006, the city of Washington D.C. passed legislation that would require green performance bonds to be

²³³ Restatement 2nd of Contracts, §356 "Liquidated Damages and Penalties"

used on construction projects beginning in 2012. This legislation was a bit confusing to industry participants who had never heard of a green performance bond and where uncertain how to acquire one (Cheatham, 2011). According to section 6b of the act:

On or before January 1, 2012, all applicants for construction governed by section 4 shall provide a performance bond, which shall be due and payable prior to receipt of a certificate of occupancy.

The bond, which could be worth up to \$3 million, would be forfeited if a building should fall short of expected green building standards (such as LEED certification) outlined within the act.

It is anticipated that Green performance bonds would function similarly to a normal construction performance bond, with the primary difference being that it covers harm specific to a projects sustainability objectives. Performance bonds guarantee the performance of the principal (“contractor”) to their obligee (“owner”). In the event of default under the terms of a performance bond the obligee will require the surety to step in the shoes of the principal and fulfill the obligation or surrender the penal sum of the bond. It is assumed that a green performance bond would function in a similar same way (Cheatham, 2011).

When it comes to green performance bonds, the bond would offer a financial guarantee that the principal will adhere to certain green building objectives. If the contractor should fail to do so, the surety would be accountable for making sure the principal fixes the problem (Cheatham, 2011). It is unclear whether the standard performance bond would cover the failure of a contractor to meet an explicit sustainability objective, or if a separate bond device will have to be created to address this risk.

Lastly, in the United States there is a groundswell of momentum behind green building and that has caused regulators and code drafters to take notice. In the near future regulators and code drafters will convert these sustainability goals from a voluntary system enforceable only under the laws of contract, to a mandatory system which becomes part of building codes subject to enforcement by local municipalities and governments. In the event that sustainability objectives become part of building codes; then in addition to the contract damages, violators could face fines and other remedies imposed by governmental authorities. This will add an additional level of risk for project participants to consider and plan for.

5 Conclusion

It is clear that sustainable construction isn’t going away anytime soon, so project participants will have to familiarize themselves with this new reality to navigate its pitfalls and risks. It seems that since the risk of failing to meet a sustainable objective is somewhat new, owners are not rigidly enforcing these conditions and contractors and architects have received a temporary reprieve. As this type of expectation becomes more common place and owners become more sophisticated it seems that owners will become less likely to ignore these provisions and allow project participants to waive all liability related to them. The next logical step for owners seeking some assurances beyond a handshake on their sustainability objectives is to include specifically tailored liquidated damage provisions in the governing contract. A properly drafted liquidated damage provision could serve the dual purpose of putting the project participants on

notice of the owner's serious intent to achieve their sustainability objectives and provide the contractor and architect some certainty as to their potential liabilities.

Defect in Building Construction Contracts. A case of liability and contractual risk

Antonio Orti Vallejo

Email: aorti@ugr.es

Abstract:

This paper aims to compare the regulations of the defects in building construction of the DCFR, Spanish Law and contracts of sale of goods on the Directive 199/44/EC, to check how the rules about defects and risks are and must be closely connected because the liability for defects depends on them. The connection shows two things which are also the conclusions. One, you cannot establish as general rule on the construction contract that the constructor could not be liable of defects caused by an event which he could not avoid or overcome. It is a risk matter. Therefore, the risk has some influence on liability for defects. Two, as a consequence of the last, the liability of constructor for defects is a hypothesis of strict liability that not require of the construction fault. This is to all remedies for defects except enforcing damages because those require the fault.

I would like to warn you this piece of work is a first draft as result of my previous publications on the subject of defects in building construction and of the sale of goods. For this reason this paper needs more profundity and should be looked at in contrast to other authors, which will explain the absence of bibliographical notes.

Keywords:

construction contract, risk, liability for defects, conformity.

1 Introduction

This paper aims to compare the regulations of the defects in building construction and contracts for the sale to check how the rules about defects and risks are and must be closely connected because the liability for defects depends on them. To achieve this goal we are going to exam three regulations. One is the Directive 1999/44/EC of the European Parliament and the Council on certain aspects of the sale of consumer goods and associated guarantees. In my opinion this is the best legal text elaborated on the subject of defects. Secondly, we will examine Spanish Law regulations on the liability for defects in building constructions. And, thirdly the Principles, Definitions and Model Rules of European Private Law also known as the Draft Common Frame of Reference (DCFR) about the similar subjects.

A general view of the regulations of defects on those legal texts show some interesting contrasts.

The Directive 1999/44/EC has broad regulations on the sale of defective goods that this legal text calls “non-conformity” instead of “defect” which is a distinctive change of name. This Directive also applies to contracts for the supply of consumer goods to be manufactured or produced which in other words means that it applies to contracts on the construction of movable things (for instance, the construction of kitchen or any furniture). The Directive does not directly establish any rule about the risk but it does indirectly and is therefore very important. With regard to Spanish Law Parliament dictated in 1999 an Act which established some extensive rules of liability for defects in building construction and a simple rule about the risks that in my view is probably wrong, as we will see. The DCFR regulates the construction contract which rules apply to the construction of buildings and movable things, but it hardly dictates any rules about the specific subject of the defects. So, it does not establish the types of defects -a very important issue-, neither the remedies for defects nor the deadlines that the client can rely on for the remedies of the defect. However, it dedicates a long article to the contractual risks.

2 The Directive 1999/44/EC on certain aspects of the sale of consumer goods and associated guarantees

I will refer to only the more relevant aspects of this Directive for the purpose of this paper. It establishes all rules that govern the defects subject for the sale of goods to the contracts signed between businesses and consumers. First of all, we have to underline that the Directive is inspired by the UN Convention on Contracts for the International Sale of Goods of Vienna 1980. It means that those rules which were drawn up to be applied to contracts between businesses but are now being applied to contracts between businesses and consumers, which, in theory require more protection. A proof of that is that the German BGB was modified in 2001 and adopted most of the rules of Directive to apply to all contracts for sale, business to business, consumer to consumer and of course business to consumer.

With regard to the Directive objective scope, as I said before, it is the contract for the sale of goods but also the contracts to construct some movable things. That is the conclusion of reading Article 1. 4. It stipulates: Contracts for the supply of consumer goods to be manufactured or produced shall also be deemed contracts of sale for the purpose of this Directive. It means that the rules of the defects to sales are also relevant for the construction contract, at least to the construction contract of movable things, because this directive only applies to the sales (constructions) of movable items.

Moreover, as already stated, in this Directive the former meaning has been changed by the use of words the “non-conformity”. This is a significant change of meaning because in European Civil Law countries the defect regulations and all that entails come from Roman law, in which the liability for the defect was dissociated from the non-performance of the seller obligations. But now the Directive follows the UN Convention the new name “non-conformity” which involves things like seller non-performance.

With regard to the types of non-conformities or lack of conformity they can be deduced by the requirements of conformity with the article 2 Directive. It establishes: The seller must deliver to the buyer (consumer) goods which are in conformity with the contract of the sale. The conformity depends on different circumstances, for instance, if they fit the description given by the seller or any particular purpose for which the buyer requires or the purposes for which goods of the same type are normally used, etc. I cannot entry go into all the extensions of this Article²³⁴. Article 2.3 Directive has some importance which declares there shall be deemed not to be a lack of conformity if, at the time the contract was concluded, the consumer was aware, or could not reasonably be unaware of, the lack of conformity. This rule is traditional in the subject of defect. It is the knowledge or not of the defect by the buyer at the conclusion of the contract which would be equivalent to a reasonable awareness.

Another aspect that I would like to refer to is about the deadline (limit?) within which the seller is liable for a lack of conformity. Article 5 establishes that the seller shall be held liable where the lack of conformity becomes apparent within two years from the delivery of the goods. This period is very important because it is in fact the legal and mandatory guarantee expiry date. In Civil law countries this period was very short²³⁵. Nevertheless, in the cases of second-hand goods the Directive allows member States to provide that the seller and consumer may agree a shorter term than two years, but such a period may not be less than one year.

Finally, the most important issue for us in this work is the rule of risk that Article 3.1 establishes. It says: "The seller shall be liable to the consumer for any lack of conformity which exists at the time the goods were delivered." At first this rule is obvious: the seller will be only liable for any lack of conformity which exists before the delivery, never a lack of conformity (defect) caused after it (for example, caused by the buyer). It is the traditional defect requirement by doctrine: liability for defects is only when the defect is original. As for the risk, this rule involves that it is passed to the buyer at the time of the goods delivery. But I would like to call attention to the fact that the seller will be liable for defects if the goods suffers some deterioration (defect or lack of conformity) before the delivery to the buyer although the defect would have been caused between the time that the contract was concluded and the delivery. Of course the seller would be liable despite the lack of conformity due to an event of which the seller cannot be held accountable. In addition I like to add that Directive establishes a rule about the burden of proof

²³⁴ Article 2. Conformity with the contract

1. The seller must deliver goods to the consumer which are in conformity with the contract of sale.
2. Consumer goods are presumed to be in conformity with the contract if they:
 - (a) comply with the description given by the seller and possess the qualities of the goods which the seller has held out to the consumer as a sample or model;
 - (b) are fit for any particular purpose for which the consumer requires them and which he made known to the seller at the time of conclusion of the contract and which the seller has accepted;
 - (c) are fit for the purposes for which goods of the same type are normally used;
 - (d) show the quality and performance which are normal in goods of the same type and which the consumer can reasonably expect, given the nature of the goods and taking into account any public statements on the specific characteristics of the goods made about them by the seller, the producer or his representative, particularly in advertising or on labeling.

²³⁵ French Civil Code in the article 1648 only refers to a short time, but does not establish something concrete; the Italian Civil Code the article 1495 establishes one year; the German BGB before the reform of 2001 established in paragraph 477 six months, like the Spanish Civil Code (article 1490).

on this aspect to profit the consumer, so if the lack of conformity becomes apparent within six months of the delivery time it is presumed to have existed at that time.

Of course the strict liability is to resort all remedies for defects except enforcing damages which will require the fault of the seller.

That is the seller liability for lack of conformity (or defect) is a strict liability or to say the same, the seller liability for defect does not need the requirement of the fault as I have said. It has always been that even from the Roman law and doctrine has never disagreed about it. However, doctrine and jurisprudence in Civil law countries like Spain have hardly ever connected the defect subject with the risk rule. This is the issue. But the Directive has served to enhance than important issue that shall serve to clear the defect liability in other contracts, like for example the construction contract.

I would like to stress a novelty rule of the Directive to Civil law countries, about the delivery time when the risk is passed to the buyer, mandatorily applied at least to the consumer contracts. The reason is that rule was absolutely contradictory to the traditional risk rule coming from Roman law: "*periculum est emptori*" in Latin. In Spain and most countries of Civil law the traditional risk rule continues to be applied to the other contracts that are between businesses and between consumers.

3 Spanish regulations of Building defects

In Spain the subject defects on construction contracts is regulated in a Act of 1999 called the Building Regulation Act -in Spanish Ley de Ordenación de la Edificación (from now the acronym LOE)-, despite its name it does not regulate the construction contract totally but one small part only. The construction contract in general is regulated in the Civil Code with very old rules coming from XIX Century. On the contrary LOE basically establishes the rules of liability for defects in building construction. But also take advantage to dictate a rule about risk which is contradictory to the general rule risk established in the Civil Code. The result is confusion about the requirements of defects liability and a big mistake.

The LOE establishes the list of people and companies who make the building, called building agents and of course the domains of each one. Basically they are the promoter, the architects and the constructor. Architect and constructor do not need any explanation or definition but the promoter probably yes. A promoter is the business developer of buildings that normally is a company, who as owner of a plot, manages, decides, contracts the other agents, invests, finances and finally sells the different houses, apartments, etc. getting the main profit. The LOE establishes the domain of each building agent in detail. Each domain is very important to distribute and determine the liability of each agent in case of any defect. This, in my opinion is not a fault issue; it is only a criterion for knowing which agent has the scope of domain, because in case of defect he could allege the defect is out his domain. If the defect is inside his domain he could never allege it was not his fault. I will come back to this. In addition we have to refer to the people who can claim liability for defects in building. They can be of course the client, but also third parties like buyers from the developer or last purchasers from the first buyer. Also the LOE allows all people refer to sue all building agents (architects, constructors, etc.).

With regard to the types of defects the LOE states three²³⁶ and at the same time establishes the different periods of building agent liability. So it distinguishes structural defects, functional defects and finished defects. The periods are ten years for the first, three years for the second and one year the last. These rules have a similar function to the sale of goods which signifies that the seller shall be held liable where the lack of conformity becomes apparent within two years to be counted from the delivery of the goods. We could enter into detail in the three types of building defects but it is a subject of singular cases which I think is not important for the aim of this paper. Only add that the time to start to count the periods is the handover of the structure.

But the main issue is how to determine the liability for defects in building or more specifically, the question would be if it is a requirement to claim the agent being at fault. Before LOE and until now it has been discussed by jurisprudence and doctrine in Spain, because some authors have held that it is a necessary the requirement of the agent fault and the courts not always have held some secure criteria about it. In addition the matter is not only in Spanish Law because in France the modification of Civil Code of 1978 established in article 1792 a exception of liability of the constructor if he proves that the damage was caused by an alien cause. That panorama has should influenced lawmakers to establish in article 17.8 LOE a similar rule of French Civil Code. It says: The liability will not be due by building agents if it is proved that the defect was caused by any event which the agents could not avoid or overcome. In my opinion this is a big mistake to form such a generalization. That would not be correct if this event had happened before the handover but if that had happened after it. Why, because it is a risk matter. So in the first case the agents still have the risk, whereas in the second the risk has passed to the client through the handover. If we would admit the agents could not be liable in the first hypothesis LOE would be absolutely contradictory with the traditional and much known risk rules in construction contract and of course in Spanish Civil Code.

In effect if we read the articles 1589 and 1590 of Spanish Civil Code about the risk in construction contract, they establish that the constructor suffers the loss or the damages and cannot claim payment of the price of the contract if they happen before the handover. In the same way, the constructor still has to perform (if it is possible) or as the case may be, perform again.

Consequently with this risk rule the agent is liable for all defects which exist in the structure at the time when it was handed over. Obviously not for the defects caused after that. In this way the client will only have to prove the defect existed at that moment, the same thing happens in the contract of sale. And of course the constructor shall be held liable where the defect becomes apparent within periods ten, three and one year from the handover of the structure stated above.

In any case these rules about defects in the construction contract are similar to the traditional defect rules of the contract of sale. As I said before doctrine has always affirmed the requirement of the original feature of defect so the seller would be liable to the buyer for it.

But the most important consequence of the primary considerations is the absolutely clear strict feature of contractual liability for defects in building construction contracts. I insist, the same thing has always happened in the sale contract dating from Roman law.

²³⁶ Like similar way French Civil Code which in this subject of liability for defect in building, in 1978 was modified in its articles 1792 and following.

In addition the same thing similarly happens in sales contracts, in construction contracts they will be deemed not to be a defect if the client was aware, or could not reasonably be unaware of, the defect. But whereas in the sale the time concerned is when to aware is when the contract was concluded, in the construction it cannot be that but the handover time. In the handover the client has the burden to inspect, supervise and accept the structure or refuse it when the structure has a defect or does not conform to the contract. Also the client can accept with an assurance cure by the constructor. On the other hand if the client accepts the structure, the constructor is relieved of liability for apparent defects although not for other defects.

4 4 The rules of the Draft Common Frame of Reference

The DCFR regulates the construction contract on articles IV.C.3.101 to IV.C.3.108 and its scope is building or other immovable structure and movable things. The DCFR only dictates an article about the specific subject of defect. It is the IV.C.3 that like the Directive 1999/44/EC uses the words “non-conformity” instead of the word defect. As I said above DCFR dictates hardly any rules about the specific subject of the defects. So, it does not establish the types of defects nor the remedies for defects or the deadlines that the client can rely for the remedies of the defect.

With regard to the remedies for non conformity, some are characteristic of all specific contracts in the DCFR. Here all the remedies for non conformity are established in general rules of the contract, inside remedies for non performance. In my opinion it is suitable. However, I do not have a favorable opinion about the lack of periods where the client can rely on a defect (“non-conformity”) and the types of non conformities because in the construction contract they are absolutely necessary. The same thing happens in the regulations of the contracts of sale. All these lacks of provisions could be resolved applying the general period of prescription of three years of DCFR article III.-7:201. But this solution would be suitable for the contract of sale and for the construction of movable things. Not for building construction because there have different types of non conformity. In relation to that, there is an overlap in DCFR between the regulations of the contract of sale and the contract of construction. In the first is a rule which, like the article 1.4 of Directive refers to the above saying “A contract that one party undertakes to manufacture or produce goods is to be considered as a contract for the sale of goods”. But if we remember the contract of construction regulation covers the movable thing, you cannot have security about what regulations apply.

With respect to the risk the article IV.C.- 3:108 DCFR establishes the rule of the risk to the constructor if the event occurs before the handover. In this case if it still possible to perform, the constructor has to perform or, as the case may be, perform again. Only in this case is the client obliged to pay for the constructor’s performance. In the case where it is no longer possible to perform the client does not have to pay for the services rendered. Finally, when an event happens after the handover the constructor does not have to perform again and the client remains obliged to pay the price. That is applied to non conformities (or defects) it will mean that the client would only have to prove that the defect already existed when the control of the structure was transferred and the constructor could not allege that it was by an alien cause. The conclusion is in any case that the liability for defects in building construction is a case of strict liability in accordance with the traditional rules of risk in the construction contract. These rules are also similar to the contract of sale as we saw before. And of course as I said to sales, the strict liability

is to resort all remedies for defects except enforcing damages which will require the fault of the constructor.

To finish I would like to do refer to the handover of structure. The article IV.C.- 3:106 DCFR regulates the handover of structure declaring that acceptance by the client of the control of structure does not relieve the constructor wholly or partially from liability. It is obvious that the acceptance does not relieve him from liability for non conformities hidden at this time. But the constructor could be relieved to apparent non conformities which the client had refused to accept. I do not understand why in this article the DCFR does not distinguish those two possibilities as it does in the regulations of sale. So in a similar way as we saw before in the Directive, Article IV.A.-2:307 declares that the seller is not liable (for non conformities) if, at the time of the conclusion of the contract, the buyer knew or could reasonably be assumed to have known of the lack of conformity. It is clear in the construction contract that the relevant time cannot be the conclusion of contract but the handover of the structure.

Global claims: a cost effective way of disposing of construction disputes?

Abstract:

This paper uses traditional doctrinal methodology to evaluate judicial statements on the merits of global or rolled up claims where it is said to be impractical or impossible to demonstrate the links between certain causes of action and the monetary value to be attached to each cause. The paper reviews key authorities from a number of jurisdictions. The key authorities are then summarised with key ingredients of the global claim authorities being identified as: impossibility, impracticability, conduct of the claimant and defendant, balance between excessive particularity and basic information, the keeping of records, the costs of claim preparation and apportionment. The Jackson Review of the costs of litigation are considered and, in that context, the paper proposes that global claims can be a cost effective way of disposing of complex construction disputes without necessarily jeopardising the basic proposition of the claimant being required to prove that to which he believes he is entitled so that the defendant knows the case he has to meet.

Keywords:

causation, cost benefit analysis, global claims, litigation

1 Introduction

Construction disputes can be very costly to resolve by litigation. Global claims are probably significantly less costly to advance than traditional claims but carry a greater risk of failure. This paper uses traditional doctrinal legal methodology to evaluate judicial statements on global claims, drawing on key authorities from a number of jurisdictions and from the realms of health and safety law and professional negligence. The paper also considers the Jackson Review of litigation costs and concludes that if a cost benefit analysis is conducted in respect of claim preparation, this paper proposes that global claims, if advanced correctly, could significantly reduce the costs of litigating complex construction disputes.

2 The Starting Point

The general rule as regards a claimant being compensated in damages for breach of contract was set out by Lord Blackburn in these terms:

*'in settling the sum of money to be given for reparation of damages you should as nearly as possible get at that sum of money which will put the party who has been injured, or who has suffered, in the same position as he would have been in if he has not sustained the wrong.'*²³⁷

In other words, the wronged party, so far as money can do it, should be placed in the same position as if the contract had been performed.

Contractors may find themselves in the position of having suffered a loss on a particular project and consider the whole of that loss is attributable to breaches of contract by the client. Contractors may then proceed, in a seemingly generalised and simplistic way, to present a claim for the total "loss" as a measure of damage which should compensate them for the harm suffered.

The claimant's right to be compensated for harm done should also be balanced up with the rights of the defendant as set out by Lord Justice Saville:

*'The basic purpose of pleadings is to enable the opposing party to know what case is being made in sufficient detail to enable that party properly to prepare to answer it.'*²³⁸

3 Review of the global claims authorities

Global or 'rolled up claims' occur when the claimant presents a claim with no breakdown in the sense that, rather than showing how each individual event has caused delay together with the monetary loss attached to each delay, the claimant provides a single claim lumping each alleged cause together without itemisation. Such an approach under normal circumstances:

*'is the antithesis of a claim where the causal nexus between the wrongful act or omission of the defendant and the loss of the plaintiff has been clearly and intelligibly pleaded.'*²³⁹

Lord Humphrey Lloyd QC also indicated 'that nexus need not always be expressed since it may be inferred.'²⁴⁰

Awards given on a global basis have, however, been supported in the context of

*'an extremely complex interaction[where] it may be **difficult or even impossible** to make an accurate apportionment of the total extra cost between the several causative events'*²⁴¹. (emphasis added)

²³⁷ *Livingston v Rawyards Coal Co* (1880) 5 App Cas.25, 39

²⁴⁰ *Bernhard's*, note 3

²⁴¹ *Crosby and Sons Ltd v Portland UDC* (1967) 5 BLR 121, QBD

The arbitrator in *Crosby v Portland* also used the word “impractical”. Similar words were used by Vinelott J, where he indicated:

a rolled up award can only be made in a case where the loss or expense attributable to each head of claim cannot in reality be separated and where apart from that **practical impossibility** the conditions which have to be satisfied before an award can be made have been satisfied in relation to each head of claim,²⁴² (emphasis added)

Awards made by both arbitrators and adjudicators on a global basis have been supported by the courts²⁴³. There have however been notable failures. An argument commonly cited against the global approach is that it amounts to an abuse of process, such an argument usually being presented at an interlocutory stage in the form of an application to strike out the claim. The abuse can be categorised as where the claimant provides no particularisation to a claim such that the defendant does not know what he is defending himself against. In *Wharf v Cumine Associates*²⁴⁴, the claimant had submitted a four hundred page document without stating their exact position and without identifying the key cause of delay. In responding to an application to strike out, the claimant averred ‘*It will be necessary at trial to consider all variations instructed in order to establish which of them are unnecessary*’.²⁴⁵

The court then concluded;

‘The failure even to attempt to specify any discernable nexus between the wrong alleged and the consequent delay provides, to use Mr Thomas’s phrase [counsel for the defendants] “no agenda for the trial”’.²⁴⁶

While Wharf could be argued to be the low point for global claims, in *Mid Glamorgan v Devonald Williams*²⁴⁷ the court reiterated the view that global claims were permissible in situations where there were issues of impossibility or impracticability:

Where however a claim is made for extra costs incurred through a delay as a result of various events whose consequences have a complex interaction that renders specific relation between event and time/money consequence **impossible or impracticable**, it is permissible to maintain a composite claim.²⁴⁸ (emphasis added)

From Wharf onwards we can see the courts reluctance to strike out global claims purely because they were presented as global claims.

The District Court of Western Australia (2007) defines the nature of a Scott Schedule as being a form of pleading which allows the court to have before it a single document. That document conveniently providing a full description of each element of claim together with the adopted positions of each party (in terms of admission or denial and quantum/evidence) to each element.

²⁴⁶ Wharf, note 8

²⁴⁷ Mid Glamorgan County Council v J Devonald Williams (1991) 8 Const LJ 61, QBD (OR)

²⁴⁸ Mid Glamorgan, note 11

In *ICI v Bovis* the claimant produced four volumes to present its case in the form of a Scott Schedule.

‘The objectives sought to be achieved by the Court in orders made relating to Scott Schedules are to ensure that when the action is entered for trial: each individual item claimed is particularised ... the amount asserted by both parties ... the contentions of each parties ... areas of agreement relating to the description of the item and quantum ... the aggregate of the claims and areas of admissions of each party are known.’²⁴⁹

The global claim in *ICI v Bovis* was still found to be deficient in many respects but permitted to proceed without further and better particulars being required. Global claims have also been permitted to proceed subject to further and better particulars being required where; the claimant’s claim was seriously defective²⁵⁰ and; where the pleadings showed no nexus between the events claimed of and the loss and damage alleged²⁵¹.

Consideration was given as to how far the claimant must go in particularising his claim in the case of *Bernhard’s Rugby Landscapes v Stockley Park*²⁵². Judge Humphrey LLoyd, restated the principles of a global claim and, while maintaining the proposition that the claimant is entitled to present its case as it thinks fit, the court must ensure a party spells out its case in sufficient particularity in order to ensure fairness and observance of the rules of natural justice. Judge Humphrey LLoyd went on to say:

What is **sufficient particularity** is a matter of fact and degree in each case, with a balance being struck between excessive particularity and basic information. The approach must also be **cost effective**.²⁵³ (emphasis added)

The Court of Appeal concluded that the core dispute, over pleadings and case management, in *Petromec Inc v Petroleo Brasileiro SA*²⁵⁴ concerned the degree of particularity with which *Petromec* must plead its case. The dispute raised questions of fairness, practicality and the appropriate means of enabling the court to define and decide issues between the parties. The court concluded that ‘it would not be fair to Petrobras, nor a practical way of the court proceeding, if *Petromec* were not required to give **adequate particulars** of their claim.’²⁵⁵ (emphasis added)

Lord Woolf and Lord Justice Otton heard an appeal against the refusal of a late strikeout application of a poorly pleaded global claim in the case of *GAB Robins v Specialist Computer Centres*²⁵⁶. The appeal was refused. Lord Woolf acknowledged that the case should have taken a different direction. He also expressed some sympathy for the trial judge and expressed hope that the judge would take into account the contribution the poor pleadings may have had on whether, to use the earlier words of Lord Justice Otton (citing with approval Judge LLoyd in *Bernhard’s*

²⁵⁶ *GAB Robins Holdings Ltd v Specialist Computer Centres Ltd* [1998] EWCA Civ 924 (8 June 1998)

Rugby Landscapes v Stockley Park), the court's fundamental concern that the dispute should be determined "***expeditiously and economically***"²⁵⁷ had been addressed.

There are warnings against the danger of a global claim failing completely if any significant part of the delay is not established and the court finds no basis for awarding less than the whole (Furst and Ramsey, 2006).

In *John Doyle v Laing*, Lord McFadden indicated that "*advancing a claim for loss and expense in global form is therefore a risky enterprise*"²⁵⁸. The risk being the global claim is undermined if either the claimant fails to prove that a material event was the fault of the defendant or, the defendant is able to prove that a material contribution to the global loss was attributable to other factors not attributable to him. Lord McFadden mitigated his analysis by providing two considerations:

'The first of these is that while the global claim as such will fail, it does not follow that no claim will succeed. but there may be in the evidence a sufficient basis to find causal connections or to make a **rational apportionment** of part of the global loss....

The second factor is that **causation must be treated as a commonsense matter**.'²⁵⁹ (emphasis added)

In terms of awarding less than the whole, Lord McFadden made it clear that "if a lesser claim is to be made out, that must be done on the basis of the evidence which is properly led within the scope of the existing pleadings."²⁶⁰

The American courts have considered total cost claims and awarded less than the whole. In *Servidone v the United States*, the claimant:

'presented evidence under the total cost method. *Servidone*, 19 Cl.Ct. at 384. Under this method, the contractor must show: (1) the impracticability of proving actual losses directly; (2) the reasonableness of its bid; (3) the reasonableness of its actual costs; and (4) lack of responsibility for the added costs.'²⁶¹

In finding that the claimant's bid (*Servidone*) was unreasonable, the Claims Court applied a modified total cost method and '*substituted a reasonable bid amount for Servidone's original estimate*.' The court also considered the effect on contractor's costs of '*performance inefficiencies*.'²⁶²

²⁶² *Servidone Construction*, note 25 paras. 9 and 10

Judge Thornton asked a number of questions in *How Engineering v Lindner* as to how the Lindner claim could be scaled down if some of the causative events alleged had been eliminated or to take account of defects, inefficiencies or events at *Lindner's* risk²⁶³.

Support for an apportionment process may be found in the words of Mr Justice Donaldson in *Crosby* who supported the arbitrators strategy in recognising that a claim does not need to be fully global or fully detailed but, that the contractor should particularise where possible and then ascertain his losses through a global claim where it was not possible by saying;

'I can see no reason why he [the arbitrator] should not recognise the reality of the situation and make individual awards in respect of those parts of individual items of the claim which can be dealt with in isolation and a supplementary award in respect of the remainder of those claims as a composite whole.'²⁶⁴

Winter argues that this type of approach reverses the burden of proof (Winter, 2007).

In order to prevent the burden of proof being reversed the claimant may be required to ensure evidence is led to indicate what his own failings might be so that the court can attribute quantum to those failings. The claimant may also be required to lead similar evidence to indicate other issues not the fault of the defendant so that, again, the court can attribute quantum to those liabilities.

A rational apportionment of the global claim or a reasoned deduction from the whole can then be made without, necessarily, reversing the burden of proof.

This paper now discusses key elements arising from the global claims authorities and considers whether a cost benefit analysis has a part to play in the advancement of global claims as being a '*commonsense approach*'²⁶⁵.

4 Impossible or impractical to particularise

The Oxford English Dictionary defines impossible, impractical and impracticable respectively as follows:

'Not possible; that cannot be done or effected; that cannot exist or come into being; that cannot be, in existing or specified circumstances.'

'Not practical; unpractical. Also = impracticable'

'Not practicable; that cannot be carried out, effected, accomplished, or done; practically impossible.'

The meanings apparently being interchangeable and absolute.

²⁶³ *How Engineering Services Ltd v Lindner Ceilings Floors and Partitions plc* unreported (QBD (OR), 17 May 1995)

²⁶⁴ *Crosby*, note 5

²⁶⁵ Commentary by the editors of the Building Law Reports on Lord McFayden's decision at [2002] BLR 396

It is worth noting that the definitions of impossible, impractical, impracticable can shed some of their absolute meaning if the meaning of impractical is taken to include the words '*not sensible or realistic*' as may be found within the 2nd Edition of the New Oxford American Dictionary.

In their Delay and Disruption Protocol, the Society of Construction Law (2002) consider the starting point with any claim is for the claimant to maintain accurate and complete records during the project so that it should be able to establish causal links between events and the loss complained about without need to resort to a global claim. In any event, with or without such records at what point does the question of impossibility arise? Is it at advancement of the claim or at trial? This question may be answered by the words of Lord McFadden in *John Doyle*:

'The rigour of that analysis is in my view mitigated by two considerations. The first of these is that while, in the circumstances outlined, the global claim as such will fail, it does not follow that no claim will succeed. The fact that the pursuer has been driven (or chosen) to advance a global claim because of the difficulty of relating each causative event to an individual sum of loss or expense **does not mean that after evidence has been led it will remain impossible** to attribute individual sums of loss or expense to individual causative events.'²⁶⁶ (emphasis added)

In some cases, the courts have balanced up the needs of the claimant to add to his case by serving further and better particulars in order to assist the defendant to understand the case he has to answer²⁶⁷.

In considering whether the claimant advances a global claim or not, it should also be recognised that such a claim is '*a risky enterprise*'²⁶⁸ particularly if absolute definitions are given to phrases such as impossible, impractical and impracticable as may be found in various judicial statements made in considering global claims. But we also see some relaxing of the absolute terms when the court uses words such as '*adequate*'²⁶⁹ or '*sufficient*'²⁷⁰ particularity.

5 Sufficient or adequate particularity

The seemingly absolute requirement of impossibility could be assimilated with an obligation to use best endeavours. To that end, should a claimant use his best endeavours and '*leave no stone unturned*'²⁷¹ either before he presents his claim or at any time through to trial? Or should he be required to use reasonable endeavours to produce adequate or sufficient particularity?

Although Judge Flaax was not convinced the distinction between best and reasonable endeavours made much difference on the facts of the case before him in *Rhodia v Huntsman*, he nevertheless addressed his mind to the distinction and appeared to conclude that best endeavours equated to all reasonable endeavours and that reasonable endeavours was a lower requirement. Some

²⁶⁶ John Doyle, note 22 para. 38

²⁶⁷ See ICI, note 13, British Airways note 2 and Holland note 15

consideration as to the cost consequences of each was not considered except in terms of sacrificing and/or acting against the parties' own commercial interests²⁷².

Time, trouble and expense are factors to be taken into consideration when weighing up whether statutory defences in health and safety law are proven (see *Coltress Iron Co v Sharp*²⁷³ and *Edwards v National Coal Board*²⁷⁴).

Here we see some discussion of a balance being struck and a question of proportionality (albeit "gross proportionality"). The health and safety authorities and published guidance do not appear to define what constitutes the distinction between proportionality or gross proportionality. What is clear in relation to the duties of a designer under the Construction (Design and Management) Regulations 2007 is that those duties to perform "so far as is reasonably practicable" are qualified by having to take:

'due account of other relevant design considerations'²⁷⁵ and, according to CDM ACOP (Managing Health and Safety in Construction, 2007), in doing so the designer should "weigh the various factors and reach reasoned, professional decisions"²⁷⁶

6 The striking of a balance

Direct guidance is provided by the Health and Safety Executive (2007) in their Policy Statement on Enforcement as to their approach of proportionality in the enforcement of health and safety law in particular:

'11. Proportionality means relating enforcement action to the risks

14. Deciding what is reasonably practicable to control risks involves the exercise of judgement.'²⁷⁷

Even though the obligation appears to be akin to an absolute obligation in health and safety law i.e. to comply so far as is reasonably practicable, there appears to be an element of proportionality and the exercise of judgement.

The standard to be expected of a professional in exercising judgement may be found in the widely recognised direction to the jury set out by Judge McNair in *Bolam v Friern Hospital Management*²⁷⁸ such that where a professional is required to exercise the ordinary skill of a competent respected practitioner in his field he will not be:

‘guilty of negligence if he has acted in accordance with a practice accepted as proper by a responsible body of medical men skilled in that particular art’²⁷⁹.

The Bolam test was modified by the House of Lords in *Bolitho v Hackney Health Authority*²⁸⁰ such that the court is required to ask whether ‘*the body of opinion relied on can demonstrate that such opinion has a logical basis*’. In particular, the House of Lords also concluded that there must be a ‘*weighing of risks against benefits, ... the Judge will need to be satisfied that the experts have directed their minds to the question of comparative risks and benefits and have reached a defensible conclusion on the matter.*’²⁸¹

This paper proposes that even where there are seemingly absolute definitions, the court leans towards a cost benefit analysis. Specifically with regard to global claims, Judge Thornton stipulated that the approach to providing sufficient particularity must be ‘*cost effective*’²⁸².

7 The Jackson Review

Judge Thornton considered *Amec*’s behaviour as against the overriding objectives of the Civil Procedure rules in determining whether its costs were reasonable or unnecessary²⁸³.

Building on the principles of access to justice enshrined in the Civil Procedure Rules, The Jackson Review (Jackson, 2009) linked access to justice, proportionate costs and practicable coming to the conclusion that:

‘Proportionate costs make access to justice practicable. Access to justice is only practicable if the costs of litigation are proportionate.’²⁸⁴

Lord Justice Jackson set out guidelines to help the Rules Committee to formulate a definition of proportionate costs which, he hoped, would bear a reasonable relationship with such matters as: the sums in issue; complexity; any additional work generated by the conduct of the paying party²⁸⁵. He also considered that oppressive conduct by wealthy litigants in putting their opponents to excessive and disproportionate costs should be sanctioned by indemnity costs with the proposed definition of proportionate costs protecting a receiving party even where indemnity costs are not awarded²⁸⁶. What is also important to consider is that Lord Justice Jackson went on to say:

‘The policy which underlies the proposed new rule is that **cost benefit analysis** has a part to play, even in the realm of civil justice.’²⁸⁷ (emphasis added)

²⁷⁹ Bolam, note 42

²⁸⁰ *Bolitho v City and Hackney Health Authority* (1997) UKHL 46

²⁸⁶ see Part 1 Chapter 3 para. 5.21

²⁸⁷ see Part 1 Chapter 3 para. 5.17 (citing *AB v John Wyeth and Brothers Ltd*, CAT 13 December 1996)

So both a claimant and a defendant are required to conduct a cost benefit analysis as to the detail and extent of their pleadings and evidence. This is particularly relevant to construction claims which can be voluminous especially where Scott Schedules are required.

8 Conduct

This paper closes on the discussion of a proposed framework by providing a reminder of what happened in *Wharf* and the effect of conduct on the outcome of proceedings in global claim cases. *Wharf* had been ordered to, and agreed to provide further and better particulars using Scott Schedules, which they did not do. To that extent, it could be argued that the failure of the global claim in this instance was not a matter of principle in respect of global claims but procedural failure and a matter of conduct of the claimant.

Conduct of the claimant was also considered in *Merton v Leach*:

‘at the time when loss or expense comes to be ascertained it is impractical to disentangle or disintegrate the part directly attributable to each head of claim, then **provided that the contractor has not unreasonably delayed the making of the claim and so has himself created difficulty** the architect must ascertain the global loss directly attributable to the two causes’²⁸⁸ (emphasis added)

The courts also commented positively on the claimant and his advisors in *ICI v Bovis*²⁸⁹ to the extent that there was ‘a total lack of any contumelious behaviour on the part of ICI or its advisors.’²⁹⁰

It would appear the Judge had certain sympathy to *ICI*’s situation however, despite *ICI*’s considerable work the defendant was still not fully aware of the case they had to meet. *Wharf* was reconsidered; their Lordships commented that if a pleading was to embarrass the fair process of trial, it could not be considered in isolation from the litigation history and to that extent, *ICI* were allowed to proceed with their claim.

The courts criticised the behaviour of the defendant in *Inserco v Honeywell Control Systems* both at first instance²⁹¹ and in the Court of Appeal²⁹². The conduct of the defendant also came under scrutiny in the case of *Amec Process v Stork Engineers*²⁹³. Judge Thornton dismissed *Stork*’s procedural objections and concluded “a fair trial was both possible and manageable.”²⁹⁴

Amec were ultimately successful with their largely global claim. On the question of costs, Judge Thornton criticised ‘*Stork*’s continuous and obstructive obfuscation’²⁹⁵ as being at the heart of its failure to produce evidence which contributed greatly to the time and costs *Amec* expended in presenting and defending the case. This case was considered to fall within ‘one of those

²⁹⁴ *Amec*, note 57

²⁹⁵ *Amec* note 47 para. 84

*exceptional cases where indemnity costs should be awarded even if there is no disapproval of Stork's conduct.*²⁹⁶ Judge Thornton nevertheless, disapproved of the manner in which *Stork's* overall case was presented and awarded indemnity costs to *Amec* in addition to being successful with their global claim.

The criticisms levelled at the defendants in *Inserco v Honeywell*²⁹⁷ and *Amec v Stork*²⁹⁸ are arguably at the heart of the Jackson Review's discussion on prolix pleadings (with specific reference to TCC proceedings) which centred around re-pleading and/or disallowing costs at the end of the case²⁹⁹. Lord Justice Jackson suggested amendments to the TCC Guide be amended to give power to the court to disallow costs in certain circumstances³⁰⁰.

9 Conclusion

The basic premise for presenting a claim in whatever form, whether it be a global claim in whole or in part, is that the defendant needs to know the case he has to meet so that there may be a fair trial of the issues.

The following ingredients for a global claim can be distilled from the authorities: impossible to particularise; impractical/ impracticable to particularise; material contribution; adequate particularity; sufficient particularity (a matter of fact and degree); striking of a balance; approach must be cost effective; dispute determined expeditiously and economically; dispute resolved fairly; causation a commonsense matter and; rational apportionment.

The global claim authorities therefore appear to indicate that the claimant need only present his claim in sufficient or adequate particularity providing a balance is struck between a claimants' right to be compensated and a defendants' right to be able to respond. Those authorities also indicate that the claim needs to be dealt with expeditiously and economically and in a cost effective manner. Cost benefit analyses are supported in decision making in health and safety law and in the law of professional negligence. The recent Jackson Review supports cost benefit analysis to civil justice.

This paper concludes that a cost benefit analysis requires a claimant to present his claim with sufficient particularity. Where that cost benefit analysis is defensible and can demonstrate the advancement of a global claim is cost effective so that the trial would be fair, a global claim should be the norm for all claims. This is particularly so where it can be demonstrated that all the events complained of are the fault of the defendant.

It may be cost effective to present even a claim that can be particularised as a global claim provided the claimant leads evidence in order to ensure an apportionment and/or appropriate deduction can be made from the globally claimed amount without compromising basic principles and/or reversing the burden of proof. The Jackson Review should also provide sufficient safeguards to protect against unreasonable conduct.

Abstract:

It is generally recognised that the UK construction industry is associated with low profit, delay in payments, cash flow concerns, insolvency, and short-term relationships compared with the other industries. In particular, claims and disputes have proliferated in the construction industry due, largely, to unfair payment practices. Therefore, to allow swift and a cheaper method of resolving construction disputes by way of adjudication, the 'Housing Grants, Construction and Regeneration Act 1996' (HGCRA) was introduced in the UK. The Act, however, has its strengths and weaknesses. To ensure the Act is more effective in achieving its intended objective, amendments have been proposed. This Paper will present the existing HGCRA 1996 Act, along with the "new" 2009 Construction Act. The Paper, based on literature review and online questionnaire survey, will discuss the level of awareness on the new Act, the perception of the UK industry on the abolition of 'contracts in writing' rule, and the key reasons for amending the HGCRA 1996 Act. The Paper concludes that the new Act is perceived as being more effective at improving cash flow in the construction supply chain and is expected to encourage parties to resolve disputes by adjudication. However, the process of integrating the proposed changes into existing dispute resolution processes is often a complex issue.

Keywords:

adjudication, Construction Act, cash flow, dispute resolution, HGCRA 1996 Act

1 Introduction

Construction industry in the United Kingdom (UK) is an important industry which accounts for approximately 9% of national gross value added and employs around 2 million people (Chappel and Wills, 2011). However, It is generally recognised that the UK construction industry is associated with low profit, delay in payments, cash flow concerns, insolvency, and short-term relationships compared with the other industries. In particular, claims and disputes have proliferated in the construction industry due, largely, to unfair payment practices. As documented in the Egan (1998) and Latham (1994) reports, the construction industry compares badly with other industries in terms of capital cost, product quality, and client satisfaction.

Furthermore, in its report on improving public services through better construction, National Audit Office (NAO, 2005) recommended that ‘unfair payment practices, such as unduly prolonged or inappropriate cash retention, undermine the principle of integrated team working and the ability and motivation of specialist suppliers to invest in innovation and capacity’. Therefore, in order to ensure prompt cash flow, improving efficiency and productivity and to allow swift resolution of disputes by way of adjudication allowing projects to be completed without wasted profit and time in litigation, the ‘Housing Grants, Construction and Regeneration Act 1996’ (HGCRA) was introduced in the late 1990s. The ‘HGCRA 1996’ is also commonly known as the ‘UK Construction Act 1996’. This Act has played an important role in improving the efficiency of construction supply chains in the UK.

The paper aims to report findings of research into perceptions of the UK industry on ‘the new 2009 construction Act’. The paper is based on literature review and an online questionnaire survey. This paper discuss the existing ‘HGCRA 1996’ Act, along with ‘the new 2009 Construction’ Act. Further, the paper will explore the level of awareness on ‘the new 2009 Construction’ Act, the perception of the UK industry on the abolition of ‘contracts in writing’ rule, and the key reasons for amending ‘the HGCRA 1996’ Act.

2 The Housing Grants, Construction and Regeneration Act 1996 (HGCRA 1996)

The ‘HGCRA 1996’ Act came into force in 1998 to reduce confrontation, facilitate better cash flow and fair play through allowing swift resolution of disputes by way of adjudication. The ‘HGCRA 1996’ Act achieves this through (CIOB, 2008): (1) providing a statutory right to refer disputes to adjudication. The adjudicator’s decision is binding until it is finally determined by legal proceedings or arbitration; (2) providing the right to interim, periodic or stage payments; (3) requiring that contracts should provide a mechanism to determine what payments become due and when, and a final date for payment; (4) requiring that the payer gives the payee early communication of the amount he has paid or proposes to pay; (5) providing that the payer may not withhold money from the sum due unless he has given an effective withholding notice to the payee; (6) providing that the payee may suspend performance where a sum due is not paid in full by the final date for payment; and (7) prohibiting pay when paid clauses which link payment to payments received by the payer under a separate contract.

Kennedy (2006) noted that in the UK, adjudication is now being used more extensively than anticipated. Various industry surveys indicated that poor payment practices are a major issue for many in the construction industry (CIOB, 2008). The ‘HGCRA 1996’ Act has generally improved cash flow and dispute resolution under commercial construction contracts, however, it is ineffective in certain key regards (DCLG, 2008). For instance, the original objectives of the ‘HGCRA 1996’ Act are being undermined by: exploitation of ‘loop-holes’ stopping the flow of money through the supply-chain; lack of clarity relating to payment resulting in adverse effects on cash flow; increased litigation; and disputes under construction contracts were threatening the viability of individual businesses and eventually would undermine the long-term health of the construction industry (DCLG, 2008). Therefore, due to some of the above inadequacies and extensive consultation with the UK construction industry and its clients, the Government has

developed proposals, which it believes will address many of the industry's concerns, particularly those of sub-contractors.

3 The new 2009 Construction Act

The main reason for amending the 'HGCRA 1996' Act was to improve the performance of the UK construction industry. The amendments (contained in Part 8 of the 2009 Act) result from concerns in the construction industry about unreasonable payment delays, and a desire to improve access to adjudication (Brampton and Hayward, 2010). The legislation including the proposed changes (The Local Democracy, Economic Development and Construction Act) received Royal Assent on 12 November 2009 and is therefore officially on the statute book (CIARB, 2010). However, it is unlikely changes to payment notice procedures and adjudication through amendments to the 'HGCRA 1996' Act will come into force in October 2011.

The new 2009 Construction Act aims to address a number of issues in the 'HGCRA 1996' Act to make the legislation more effective at improving cash flow in construction supply chains (e.g. reducing unfair payment practices such as unduly prolonged or inappropriate cash retention in the construction industry) and to encourage parties to resolve disputes by adjudication (e.g. reducing restrictions or disincentives). However, the new Act seeks to address some of the issues and grey areas raised by a decade of case law on the 'HGCRA 1996' Act. However, critiques argue that many of the 'HGCRA 1996' Act grey areas had already been addressed by the common law and therefore the new Act adds nothing new.

4 Research Methodology

The main aim of this research was to produce a valuable insight into some of the key issues and challenges do the UK industry facing with the abolition of 'contracts in writing' rule in Section 107 of the 'HGCRA 1996' Act. In order to achieve the aim of this research, a robust methodology is essential. According to Hughes and Sharrock (1997) research is defined as the process of discovering something that is not already known. It is a reasoned process done with scrupulousness, with rigour, with careful weighing of evidence and the arguments, with some methodology. According to Dainty (2007), the choice of research methodology is a crucial and difficult step in the research process. Hussey and Collis (2003) define methodology as the overall approach to the research process, from the theoretical underpinnings to the collection and analysis of the data. Therefore, research methodology in social enquiry refers to far more than the methods adopted and encompasses the rationale and philosophical assumptions that underlie a particular study. These, in turn, influence the actual research methods that are used to investigate a problem and to collect, analyse and interpret data.

Given the relatively new and unexplored nature of the research problem, quantitative research method was adopted to collect and analyse data. A web-based, an online questionnaire survey method was employed to collect data. This method of data collection have many advantages including low cost, speed, and ability to reach respondents anywhere in the country, according to Punch (2005). The sampling technique used for data collection for this survey was a convenience sample, rather than random sampling. This is because there is no comprehensive, nor any standard, database of UK organisations involved in construction dispute resolution.

Survey invitations were e-mailed to respondents requesting to submit their views via an online survey hosted at <http://www.survey.bris.ac.uk/uclan/construction> which was live from 06/12/10 to 08/04/11. Using this method of data collection, a total of 102 fully completed and usable questionnaires were received. Of them 71% (72 of the 102 respondents) were from Small and Medium Sized organisations (SMEs) (employee size between 1 and 250) and 29% (30 of the 102 respondents) were from large organisations that have employee size of 251 and above. The survey respondents include: arbitrators, main contractors, construction lawyers, adjudicators, claims consultants, project managers, delay experts, sub-contractors, and quantity surveyors. Saunders et al. (2003) argue that a minimum number (i.e. effective responses) for statistical analysis should be 30. Therefore, the statistical analysis of 102 responses collected in the current study is seen as reasonable and effective, especially for a survey of this kind.

5 Findings and Discussion

Analysis of online survey responses suggests the following insights.

5.1 The level of awareness on the new 2009 Construction Act

It is possible that having an awareness of ‘the new 2009 Construction Act’ contributes highly to the development of a successful implementation strategy. As shown in Figure 1, at the aggregate level, 88% of the survey respondents indicated that they had some awareness of the new Act.

Figure 1. Awareness among respondents of ‘the new 2009 construction Act’

However, 12% maintained that they had no understanding of the new Act. Indeed, the current survey results clearly show that there is a relatively high level of awareness among the UK industry regarding the new Act. This is a ‘welcome progress’ made by the UK industry.

Figure 2.
Awareness of 'the new 2009 construction Act' among respondents based on organisations size

Figure 2 shows the dis-aggregated responses from SMEs and large organisations awareness of the new Act. A comparative analysis has shown that between SMEs and large organisations the differences are very minor. Furthermore, in this study, through online survey, respondents were asked to indicate the level of awareness of 'the new 2009 Construction Act' on a four-point Likert scale ranging from 'very well informed'; 'fairly well informed'; 'little informed'; and 'not at all informed'.

Figure 3. Level of awareness of 'the new 2009 Construction Act' among respondents

Figure 4.

Level of awareness of 'the new 2009 Construction Act' among respondents based on organisations size

As shown in Figure 3, at the aggregate level, 39% of the survey respondents indicated that they had very well informed of the new Act. However, 21% claimed that they had fairly well informed of the Act while 28% of the respondent indicated that they had little and 12% claimed that they had not at all informed. From the above results, it appears that there is well informed of the new Act among the survey respondents. However, still 40% of the survey respondents believe that they had little or not at all informed of the new Act.

Figure 4 shows the level of awareness of the new Act between the SMEs and large organisations. A comparative analysis has shown that between SMEs and large organisations, the level of awareness of the new Act varies. For instance, 35% of the respondents from SMEs and 43% from the large organisations indicated that they had little or not at all informed of the new Act. For successful implementation of the new Act, wider awareness-raising across organisations is critical. For those members who are not yet familiar with the new Act and for those companies are not yet prepared, it is strongly recommended that contractors and employers begin the process of updating their existing contract precedents and schedules of amendments to bring them in line with the new Act as soon as possible. It is also important to be familiar with the intended changes that will impact on contracts once the new Act comes into force.

It is therefore advised that an industry-wide awareness-raising programme on the 'new 2009 Construction Act' needs to be developed and deployed. Guidance and awareness-raising can combat some of the practical difficulties in implementing the new Act to an extent. However they cannot eliminate them completely. Furthermore, the existing education and training programmes need some reorientation; the syllabuses should cover aspects of reasons for amending the 'HGCRA 1996' Act, affect of the proposed changes to the 'HGCRA 1996' Act on the adjudication process, key challenges to the adjudication process with the abolition of 'contracts in writing' rule and the impact of the abolition of 'contracts in writing' rule has on the adjudication process in the UK construction industry. The challenge, therefore, is for construction law related schools and adjudication consultants to bridge the gap in the market

place. Continuing Professional Development (CPD) programmes and executive training programmes are valuable ways to raise awareness of the new Act.

5.2 The perception of the UK industry on the abolition of ‘contracts in writing’ rule

One of the most important proposed amendments to the ‘HGCRA 1996’ Act is the repeal of Section 107 of the ‘HGCRA 1996’ Act, which provided that only construction contracts made ‘in writing’ or ‘at the very least evidenced in writing’ could be adjudicated (CIArB, 2010). As shown in Figure 5, at the aggregate level, 84% of the survey respondents indicated that they had aware of the abolition of ‘contracts in writing’ rule in the new Act. However, 16% indicated that they had not aware of it. These findings suggest that the UK construction industry organisations are well aware of the abolition of ‘contracts in writing’ rule in the new Act.

Figure 5. Awareness among respondents of the abolition of ‘contracts in writing’ rule in ‘the new 2009 Construction Act’

Figure 6.

Awareness among respondents of the abolition of ‘contracts in writing’ rule in ‘the new 2009 Construction Act’

From Figure 6, it is clear that the level of awareness of the abolition of ‘contracts in writing’ rule in the new Act between SMEs and large organisations is less. Furthermore, in this study, respondents were asked to indicate their perception of the abolition of ‘contracts in writing’ rule in the new Act is good, or bad, or of little insignificance/relevance for their businesses.

Figure 7. Perception among respondents of the abolition of 'contracts in writing' rule in 'the new 2009 Construction Act'

Figure 8. Perception among respondents of the abolition of 'contracts in writing' rule in 'the new 2009 Construction Act' based on organisations size

As shown in Figure 7, at the aggregate level, 60% of the survey respondents indicated that the abolition of 'contracts in writing' rule in the new Act is good for their businesses. However, 40% of respondents perceive that the abolition of 'contracts in writing' rule in the new Act is of little significance/relevance or bad to their business.

Furthermore, from Figure 8, 63% of the respondents from SMEs believe that the abolition of ‘contracts in writing’ rule in the new Act is good, 11% believe it bad and 26% percent believe it of little significance/relevance to their businesses. While 54% respondents from large organisations perceive that the abolition of ‘contracts in writing’ rule in the new Act is good, only 3% perceive it bad and 43% percent perceive it of little significance/relevance to their businesses. Form the above analysis it is clear that the perception of SMEs and large organisations of the abolition of ‘contracts in writing’ rule in the new Act varies.

Lal (2008) noted that, Section 107 of the HGCRA 1996 has ‘wasted money, wasted adjudicator and court time’ and has lead to ‘jurisdictional attacks on adjudicators that have nothing to do with the merits of the referring party’s case’. The requirement for construction contracts ‘in writing’ as a precondition for adjudication has been repealed in full from the new Act. Therefore, it is good for the industry. However, Phillpott (2009) noted that adjudicators will be faced with the difficult task of trying to sort out what the contract terms were that were agreed and will pose challenges to the Adjudicator in the assessment of witness evidence because it is likely that hearings will become more common.

5.3 Key reasons for amending the ‘HGCRA 1996’ Act

Various amendments have been proposed to the ‘HGCRA 1996 Act’ to improve the efficiency and productivity of the UK construction industry (BERR, 2008). Through the online survey, respondents were asked to indicate the level of importance they attribute

Table 1. Key reasons for amending the ‘HGCRA 1996’ Act

Key reasons	All respondents		SMEs		Large	
	Mean values	Rank	Mean values	Rank	Mean values	Rank
To allow swift resolution of disputes	1.55	1	1.58	2	1.50	1
To improve the enforcement of the adjudicators’ decisions	1.65	4	1.63	4	1.69	4
To encourage parties to resolve disputes by adjudication	2.02	8	2.06	9	1.93	7
To make the legislation more effective at improving cash flow in construction supply chains	1.59	3	1.62	3	1.53	2
To improve the right to suspend performance under the contract	1.99	7	2.01	8	1.90	6
To abolish ‘contracts in writing’ rule	2.13	9	1.98	7	2.50	9
To reduce unreasonable payment delays	1.57	2	1.54	1	1.66	3
To improve access to adjudication	1.85	6	1.80	6	2.00	8
To reduce unwarranted litigation	1.81	5	1.79	5	1.86	5

to each key reason for amending the ‘HGCRA 1996 Act’ on a four-point Likert scale ranging from “very important (1)”, “important (2)”, “fairly important (3)” and “not at all important (4)”. Their responses have been averaged, and are presented in Table 1.

It is apparent from Table 1 that, with a mean value of 1.55, 'to allow swift resolution of disputes' is the single most important reason for amending the 'HGCRA 1996' Act. 'To reduce unreasonable payment delays' placed second as a key reason to amend the 1996 Act. It was followed closely by 'to make the legislation more effective at improving cash flow in construction supply chains' and 'to improve the enforcement of the adjudicators' decisions'. However, to abolish 'contracts in writing' rule and to encourage parties to resolve disputes by adjudication are the least important reasons for amending the 'HGCRA 1996' Act.

It is evident from the above results that to allow swift resolution of disputes by way of adjudication allowing projects to be completed without wasted profit and time in litigation is a key reason for amending the 'HGCRA 1996' Act. According to Uff (2009) speed is an important criterion for an effective dispute resolution system. Speed ensures that the overriding objective of expediting the recovery of payment debt is not defeated. Therefore, the timescale afforded to resolve a particular dispute must be reasonable.

Further analysis of Table 1 reveals that the key reasons for amending the 'HGCRA 1996' Act varies between SMEs and large organisations. For instance, for SMEs 'to reduce unreasonable payment delays' is the key reason for amending the 'HGCRA 1996' Act while 'to encourage parties to resolve disputes by adjudication' is the least important reason. It is understandable that in an environment where the economy is volatile, large banks which are dominant sources of capital for projects would have little appetite for whole-sale-type financing. This might make it difficult for SMEs to secure funding. According to Davis (1991) for SMEs cash flow problems are a major source of insolvency. Therefore, in this study respondents from SMEs believe that amendments to the 'HGCRA 1996' Act could reduce unreasonable payment delays. Whereas for large organisations 'to allow swift resolution of disputes' is the single most important reason and 'to abolish 'contracts in writing' rule' is the least important reason for amending the 'HGCRA 1996' Act. Building and preserving long term relationship with customers and suppliers is of paramount importance, according to Latham (1994). Prompt and fair payment practice throughout construction supply chains to better enable the industry to adopt integrated working culture. Therefore, amendments to the 'HGCRA 1996' Act is sensible. However, it is difficult to justify the costs and uncertainty that will come with the changes. Costs can mean legal/expert costs as well as adjudicator's fees.

6 Conclusion and Further Research

The proposed 'new 2009 Construction Act' aims to address a number of issues in the 'HGCRA 1996' Act to make the legislation more effective at reducing unfair payment practices such as unduly prolonged or inappropriate cash retention in the construction industry and encouraging parties to resolve disputes by adjudication. If the new Act comes into force, there will be significant impact on the adjudication and payment method in the UK construction industry.

The paper is based on literature review and quantitative data obtained from 102 completed online survey questionnaires. This paper has explored the existing 'HGCRA 1996' Act, 'the new 2009 Construction Act' as well as the level of awareness of 'the new 2009 Construction Act'. Further the paper explored the perception of the UK industry on the abolition of 'contracts in writing' rule and the key reasons for amending the 'HGCRA 1996' Act. The study reveals that that there is relatively high level of awareness among the UK industry of the new Act and it appears that

the industry is well informed about the new Act. Difference in the level of awareness of the new Act between SMEs and large organisations is minor. This is a ‘welcome progress’ made by the UK industry. However, it is going to be very challenging for the industry to understand amendments to the ‘HGCRA 1996’ Act. Furthermore, the study results suggest that the UK Construction industry is well aware of the abolition of ‘contracts in writing’ rule in the new Act and the industry perception is that is good for their businesses. Difference in the level of awareness of the abolition of ‘contracts in writing’ rule in the new Act between SMEs and large organisations varies. As revealed by this study, the three key reasons for amending the ‘HGCRA 1996’ Act include: to allow swift resolution of disputes, to reduce unreasonable payment delays and to make the legislation more effective at improving cash flow in construction supply chains. The key reasons for amending the ‘HGCRA 1996’ Act varies between SMEs and large organisations.

The paper concludes that the new Act will be more effective at improving cash flow in construction supply chains and to encourage parties to resolve disputes by adjudication. However, the process of integrating the proposed changes into existing dispute resolution processes is often a complex issue. The construction industry employers, main contractors, sub-contractors and their respective advisers will need to adopt and become accustomed to quite significant changes on the adjudication and payment practices. It is therefore advised that an industry-wide awareness-raising programme on the new Act needs to be developed and deployed. Furthermore, the existing education and training programmes need some reorientation. Given that the research reported in this paper is based on small sample, hence, the results presented here are only tentative. Therefore, it is advocated that additional research should explore the complex issues associated with amendments to the ‘HGCRA 1996’ Act. The nuances, which should focus on capturing the critical tensions and the impact on the adjudication process in the UK construction industry.

United Kingdom

Email: florence.walker@ucl.ac.uk; s.pryke@ucl.ac.uk

Abstract:

The results presented in this paper have been produced as part of an ongoing study to model the impacts of construction documentation incompleteness on claims management. The research project examines both the antecedents (primitive project characteristics of interorganizational relationship (IOR) governance mechanisms, i.e. Uncertainty, Asset Specificity, and Frequency of trade between parties) and consequences (Claims Management, in this case) of governance structure. There is a need to understand governance structure antecedents and consequences to better assist modern project management. This paper reports on development of measures of: the Frequency antecedent and its impacts on the corresponding IOR governance mechanisms developed to manage projects.

Due to the sensitive nature of the information required for this research, data collection has been a primary concern throughout. Also, given the dynamism and practical concerns (confidentiality, ease of collection or provision, cost, time, etc.) of the research process, careful consideration has been given to acquiring an appropriate data set which would permit rigorous testing and analysis to address the research questions. Throughout, the aim has been to maximize response rates and quality of data obtained. Therefore, an effort is also made to outline the considerations behind development of clear and precise questions to elicit data and information about the Frequency antecedent and its impacts that was readily available to the respondents (a professional body of construction lawyers).

Keywords:

frequency, measurement, construction interorganizational relationship governance mechanisms

1 Introduction

Research examining the way in which construction contract design and structure shape interorganizational dispute resolution processes is currently underway. Ultimately, the research aim is to understand how reliance on contractual governance will impact dispute resolution processes and outcomes. Overall, the research explores how the degree of construction documentation incompleteness influences interorganizational behaviours after conflict has arisen (i.e. when a primary objective of interorganizational relationship (IOR) governance fails) and

when and how contracts will be effective in reducing destructive interorganizational conflict. Relevant to this endeavour is an examination of antecedents of UK construction industry IOR governance structures and their outcomes, in order to control for various attributes of the IOR and of the resulting conflict and disputes. Therefore a useful place to start when evaluating the efficacy of contractual governance in resolving disputes would be to develop a thorough understanding of the influence of the antecedents on governance design. This article aims to refocus the study on these antecedents and resulting governance structures with a particular focus on how a prior relationship based on the Frequency of trade between contracting parties affects the resulting contractual governance structure; while raising questions about implications for research design. A professional body of lawyers has been consulted to provide the necessary data in the form of responses to survey questions. With this understanding, suitable practical data acquisition strategies have been devised.

2 Literature Review

Reviewing the extant literature on design of IOR governance structures, we see that there is a wide variety of mixed forms of contracts, in between the two hierarchical and market governance extremes. Winch (2010), building on Macneil's (1974) groundbreaking contribution to the theory of contracting, explains that governance has two distinct aspects: the contractual (capturing the legal basis of the relationship), and the relational (which captures interpersonal and interorganizational aspects). Contractual and relational governance are not mutually exclusive and theorists (Poppo and Zenger, 2002; Gulati and Nickerson, 2008) have argued that parties should, ideally, rely on both mechanisms to manage relationships. However, more often than not, there is evidence of relational considerations in the written documentation that embodies the legal basis of the relationships. For this reason, our research depends on the evidence presented by the written documentation to detect both contractual and relational considerations.

From the literature, we also see that contract documentation packages vary in their intent and detail (Macaulay, 1996). The process by which construction industry firms choose from among the variety of governance designs available to them has been the object of numerous studies in strategy and organizational theory (Williamson, 1985; Pisano et al., 1988; Gulati, 1995; Winch, 2010). Lumineaux and Malhotra (2011) provide a good summary of how IOR antecedents influence governance structures. They explain that firms rely on a variety of governance mechanisms to mitigate risks of opportunistic behaviour and promote cooperation. Therefore, some documentation packages contain large numbers of provisions, while others seek to codify as little as possible. Others focus heavily on the need to mitigate the risk of opportunism and include many provisions, the aim of which, are to control parties' behaviours (Williamson, 1985). Additionally, contracts may focus on ensuring that parties have a shared understanding of the relationship so that they can optimally coordinate their efforts (Salbu, 1997; Mellewigt et al., 2007). Also, the research recognizes that contracts are inevitably incomplete (Grossman and Hart, 1996; Williamson, 1996). Some are incomplete due to bounded rationality (BR) (parties not knowing precise conditions under which contracts will be executed (Winch, 2010) – making it impossible to delineate all potential future contingencies (Simon, 1961; Malhotra and Murnighan, 2002). Others may be incomplete by design: some parties will choose to limit their reliance on contractual governance even when greater contractual detail is possible. (Lumineaux and Malhotra (2011) outlined three reasons why parties may choose to limit their reliance on

contractual governance. First, parties may want to minimize contract development, monitoring, and enforcement costs (Williamson, 1985). Secondly, parties may wish to allow for greater strategic flexibility, recognizing that additional information regarding each party's needs, interests, and capacities will be uncovered over time (Bernheim and Whinston, 1998; Malhotra, 2009). Third, parties may wish to encourage development of mutual trust and cooperative norms which can be 'crowded out' when too much emphasis is placed on contractual governance (Sitkin and Roth, 1993; Tenbrunsel and Mesick, 1999; Malhotra and Murnigan, 2002).

There is broad coverage of the antecedents' influences, however, the literature has not devoted attention to analysis of the material presented to provide practical guidance for designing instruments for eliciting the necessary information to achieve general research objectives. Therefore, we propose a framework for instrument design for our research endeavours. We draw inspiration from Furlotti (2007) to devise a systematic approach for reviewing the literature to identify recurring themes for antecedent impacts to guide instrument design and content, and operationalize our constructs for acquiring the data to populate our overall research model.

Our overall model incorporates Oliver Williamson's (1975, 1985) model of transaction costs and governance structures, as Winch (2010) has applied it to IORs in the construction industry. Winch (2010) explains Williamson's (1975, 1985) arguments that the most efficient relationship governance mode for interorganizational transactions is determined by three main transaction characteristics: Uncertainty, Asset Specificity, and Frequency. Uncertainty, affects IORs because it creates BR for decision-makers. BR makes writing complete and unambiguous contract documentation impossible because of uncertainty about precise conditions under which contracts will be executed, and makes it impossible to fully measure contract performance. Asset Specificity describes the degree to which investments are specialized to a particular transaction and results when either the buyer or the supplier is limited in their choice of transaction partner because of the specific nature of the resources to be supplied. Asset Specificity may exist pre-contract (*ex ante*) (market monopoly or monopsony), or may be generated post-contract (*ex post*) because of specific investments made by either party. This generates the possibility of opportunism, where one party tries to exploit the other's disadvantage – often by withholding information from the other party. Through threats to terminate the relationship, opportunistic partners can seek to re-negotiate the transaction terms to their advantage. Frequency affects transaction governance because one-off transactions provide no opportunity to learn about the other party, while repeated transactions allow learning and in some cases, trust generation (Munns, 1995; Munns, 1996; Mellewigt et al., 2007; Winch, 2010). Thus, the most efficient governance mode can be thought to occupy a three-dimensional space (See *Figure 1a*) and therefore, in our model, the IOR governance design, embodied in the contract documentation package can be represented as being directly influenced by these primitive interorganizational transaction characteristics (inter-firm governance antecedents) (See *Figure 1b*).

Relationship Governance Design

2.1 A Note on the Frequency Characteristic

The economics literature on Uncertainty and Asset Specificity impacts on contractual governance design is extensive and comprehensive (Klein, 2006). Conversely, testing of the Frequency antecedent to indicate how past transactions affect inter-firm relationship governance is rather scarce (Klein, 2006; Furlotti, 2007). Klein (2006) explains that Frequency appears in three distinct, and seemingly incompatible, forms: a) Frequency of Trade Between Specific Trading Partners; b) Frequency of Trade Among Many Trading Partners; and c) Frequency of Disturbances in the Environment. This research explores the first form – Frequency of Trade Between Specific Trading Partners. This is the repeated-game notion of Frequency (Klein, 2006), as described by Williamson (1985, p. 62) and Baker et al. (2002) and hereinafter, will be referred to simply as Frequency.

The relative rarity of encountering empirical evidence of Frequency impacts on governance design, has prompted some theorists (Casciaro, 2003) to argue that the research agenda seems to be less concerned with the Frequency contribution of trust, learning, and evolution to IOR relationship governance. However, anecdotal information provided by a prominent economic theory academic suggests that this lack of treatment and exclusion from analyses may actually be due to the fact that theory of contract researchers are still unsure of the exact way in which Frequency influences IORCG design. Review of this status of understanding of the Frequency contribution provides the impetus for this research direction on this particular occasion. Moreover, we are unaware of any comprehensive reviews of the state of understanding of Frequency impacts from evidence generated through study of Frequency impacts on construction industry project transactions. This allows us to uncover considerable, but unevenly distributed evidence of Frequency impacts on a number of overlapping contractual dimensions (measurable contractual attributes that are separate and distinct from individual contract terms) as described by different fields of IORCG theory. It also enables description of contracts in a larger number of dimensions than is commonly appreciated. Consequently, we believe that our decision to restrict our focus here to the Frequency antecedent makes an important contribution.

3 Research Methodology

The research methodology entails a literature review of empirical studies of formal contract design in IORs. Due to the complex nature of construction contracts (resulting from Asset Specificity in all but the simplest projects) systematic analysis of their dimensions is necessary for thorough understanding of Frequency impacts. This analysis draws inspiration from and extends the contribution to the legal and economic theories of contract made by Furlotti (2007), who proposed a general and tentative framework for relational contract design by summarizing empirical evidence on contracts. The review considers evidence presented in the Organizational Theory, ICT, TCE, Agency Theory, and Strategic Management literatures on interorganizational relationships (IORs). Through this summarizing process, Furlotti (2007) explained how contracts operate in practice. This was achieved by highlighting the multi-dimensional character of contractual incompleteness while emphasizing extra-contractual governance devices that complement formalized contract documentation.

Therefore, the considerable thrust imparted by Furlotti (2007) to our analysis is in the form of a systematic methodology for assessing impacts of Frequency on the structure and content of formalized contract documentation, as well as on some associated extracontractual governance devices presented in the evidence from the empirical studies reviewed. Our methodology and sampling criteria is similar to that deployed by Furlotti (2007) in that we focus our search, on articles written in the last decade, only making exceptions when we feel that particular contractual design processes are underrepresented in recent literature. Also similar to Furlotti (2007), our review focus will only be on empirical studies of formal contract design in IORs; i.e. studies based on observation of real-world contracting, either by means of documentation analysis, or by case studies, interviews, or questionnaire survey. Rather than reviewing studies that take contract terms for granted, we focus on studies wherein the parties are responsible for designing their own agreements. We review only those studies that have been cited more than 3 times in high-impact journals by recognized theorists on the subject. By reviewing only empirical studies of IORs, we do not review tests or exploratory investigations of contracting theories based on experimental approaches, nor does our review cover other fields such as employment contracts. Also, by selecting only studies published in high-impact journals, we ensure that our review subjects are topical and influence the current thinking on Frequency. Although achieving comprehensiveness is not our preoccupation at this stage, we trust that not many important articles strictly fulfilling the above-stated criteria have escaped our search.

Our review isolates specific Frequency impacts on some identified IOR contractual governance (IORCG) dimensions, in turn, and discusses the associated implications for research instrument design and survey instrument content. We build on Furlotti's (2007) work by reviewing literature excluded from Furlotti's (2007) analysis – mainly due to non-existence at the time of his review. In presenting our review of Frequency impacts, we are guided by Furlotti's (2007) explanation of contractual dimensions and his approach to assessing how the dimensions are sensitive to the primitive project characteristics (antecedents).

4 Findings and Discussion

Interestingly, the few studies that have investigated this Frequency form have been largely drawn from technological industries (IT, high technology, and biotechnology R&D). A summary of the results from our review are presented in Table 1 (*in the Appendix*).

4.1 Theoretical Perspectives on IOR Contractual Governance Design

This review uncovered a number of accounts of the processes encompassed by relational contracts and their associated theoretical perspectives on IOR governance design, namely: Strategic Management, Organizational Theory (OT), Incomplete Contract Theory (ICT), and Agency Theory. Review of these theories should prove instructive, fostering better appreciation for our rationale for contractual design evidence categorization and systematic analysis.

4.1.1 *Theoretical Perspectives of Frequency Impacts supported by Empirical Evidence*

Our review also, indirectly exposes the genealogy of this understanding of Frequency impacts and the theoretical perspectives that underpin them. (*See Table 1*). The main empirical evidence contributions that fit our criteria described above for explaining how contracting parties' working history influences IORCG design is provided by scholars who examine: the way in which firms learn to develop governance arrangements (Mayer and Argyres, 2004); the effects of prior alliance experiences with the same partner, or with any partner, on the management of the collaboration (Hoang and Rothaermel, 2005); impacts of prior experiences on the choice of strategic alliance type (Gulati, 1995), on contract changes (Argyres et al., 2007; Mayer and Argyres, 2004; and Reuer et al., 2002) and on alliance structure and outcomes (Sampson, 2005; Zollo et al., 2002). Mellewigt et al. (2007); Vanneste and Puranam (2010); and Dekker and Van den Abbeele (2010) also provide other compelling post-Furlotti (2007) evidence of ways in which firms learn and acquire knowledge to inform governance choices.

Dekker and Van den Abbeele (2010) adopt a Strategic Management perspective on IORCG design and noted the seemingly paradoxical nature of Frequency impacts. Some scholars (Gulati, 1995; Gulati and Nickerson, 2008; Zollo et al., 2002) report that firms with prior ties use less extensive governance structures for new exchanges, compared to firms without joint histories. This is attributed to familiarity and trust generated during prior interactions that reduce the need for control. Conversely, others (Ryall and Sampson, 2009; Argyres et al. 2007; Mayer and Argyres, 2004; Poppo and Zenger, 2002) have observed that interactions over time with an exchange partner and increasing relational governance entail important learning effects that facilitate (cost-efficient) development of control structures. The most recent Frequency evidence suggests that by facilitating both trust development and learning, partner experience thus can have opposite offsetting effects on IORCG design.

We were guided in our measurement of Frequency by Vanneste and Puranam (2010), who noted that obtaining the precise number of prior interactions in survey-based studies is difficult. We, therefore, relied on respondents' estimates of the number of times they interacted with their co-disputant in the past on a six-point scale ranging from 'never' to 'many times'. The response to this item is corroborated with another survey item designed to capture estimates of the volume of business in prior transactions with the co-disputant.

4.1.2 Strategic Management Theory view of Contracts

Mellewigt et al. (2007) highlight the two prominent theoretical perspectives recurring in the recent Strategic Management literature on IORs, namely: TCE, and the Resource-Based (RB) view. TCE and RB perspectives primarily assign a control and coordination function, respectively, to contract design, and therefore, it is important to recognize the dual function of contracts bestowed by Strategic Management theory. TCE is motivated by efficiency considerations and mitigation against opportunism and (mis)appropriation of value by counterparties. The general consensus is that transaction characteristics translate into exchange hazards, which might be managed by drawing more complex contracts (Williamson, 1975, Nooteboom et al., 1997). If firms make specific investments, they put themselves at risk of value appropriation by potentially opportunistic counterparties (Klein et al., 1978) since the specific asset is of little use outside of the relationship. Essentially, contracts incorporate safeguards to control against opportunism risks that may result from transaction hazards, such as Asset Specificity. This is manifested through more contractual details and stipulations. Formal contractual provisions protect against self-interested counterparty behaviour and function as controlling devices.

Methods to measure usage of Outcome and Behaviour Control mechanisms can be based on those used by Dekker and Van den Abbeele (2010) who followed precedents set by Jaworski and McInnis (1989) and de Mortanges and Vossen (1999). Outcome Control functions without interference in suppliers' processes and is measured by five items about the extent to which the buyer, during transaction management, engaged in target-setting, evaluation and rewarding of outcomes, and provision of feedback to the supplier. Behaviour Control is measured by six items about the procedures specified and used to achieve certain goals, not necessarily focusing on the extent to which the buyer monitored the supplier's use of procedures, required reports, provided feedback, and shared in costs if guidelines were followed.

From the RB perspective, an IOR enables two organizations, to attain some mutually beneficial outcome through sharing and combining resources in a manner that they could not attain on their own (Madhok and Tallman, 1998). Here, the challenge is organizing value creation processes by coordinating respective resources across organizational boundaries and contracts serve as coordinating devices. For instance, contracts clarify mutual expectations, enable goal congruence, and establish bases for shared common ground (Das and Teng, 1998). More specifically, delineation of roles, rules, programs, and procedures enables coordination of interfaces that are often necessary for joint endeavours to successfully accomplish collective goals (Mayer and Argyres, 2004). There is a change between perspectives - from value appropriation under TCE, to value creation under RB. Whereas contractual control mechanisms tend to mitigate relational risks, coordination mechanisms tend to address performance risks (the probability and consequences that alliance objectives are not achieved, despite a satisfactory cooperation among partner firms (Das and Teng, 1996)). IOR performance risks and their associated coordination requirements vary systematically, with the extent and importance of the shared resources (Borys and Jemison, 1989; Kumar and Seth, 1998), because execution of activities involving more strategically important resources and services directly influences other organizational services and resources as well as the partnership's collective goals. Contracts incorporate various types of coordination mechanisms to handle heightened concerns of strategic importance in IORs. Contract clauses can precisely enumerate the tasks to be accomplished,

define procedures to be used and lay out quality standards to be fulfilled. Alternatively, contracts can specify the decision rights in IORs and may structure communication flows in a decisive way. With construction projects becoming increasingly valuable and complex endeavours that entail greater interdependence, the coordinating role is correspondingly, becoming increasingly important to the IORs formed. This has important implications for design of contractual governance structures for the effective management of IORs.

According to Lumineaux and Malhotra (2011) the first two terms of Parkhe's (1993) eight-term index developed for evaluating formal contract provisions relate to Coordination between contracting parties, and may be used as a proxy for the degree to which the parties focus on coordinating their expectations and behaviours. (Interested readers should consult Parkhe (1993) and Lumineaux and Malhotra (2011) for the complete list.) Coordination focus is, therefore, measured as the ratio of coordination-related clauses included in contracts, i.e. clause categories about i) Periodic written reports of all relevant transactions and/or ii) Prompt written notice of any departures from the agreement, to the total number of provisions in the contract. By controlling for the total number of clauses, the ratio measure mitigates concerns that coordination provisions were included incidentally (due to institutional factors that promote greater contractual detail), rather than deal with coordination issues. Moreover, by assessing the percentage of the contract devoted to coordination, the measure captures the extent to which the contracting process is motivated by a focus on coordination.

4.1.3 Organizational Theory View of Contracts

Furlotti (2007) provides a good explanation of the Organizational Theory perspective on IORCG choice. In developing Stinchcombe's (1985) hypothesis that contracts are an organizational phenomenon, Furlotti (2007) identified a number of IORCG processes and dimensions and reviewed regularities uncovered. He set out from the observation that contracts (usually regarded as market transactions) were observed in some situations when TCE would expect integrated structures (in-house procurement routes). For those situations, his central premise was that contracts perform the same functions as integrated structures. Here, contracts incorporated similar mechanisms more frequently observed in organizations, such as: norms, rules, negotiation, voting, authority, etc. In turn, as these mechanisms are of a different type, and perform different functions, they need not correlate with a single contractual dimension (e.g. Completeness). Thus, contracts act like complex organizations. IORCG involves coordination and procedural aspects well-known to the organizational literature and Furlotti (2007) saw it necessary to study project antecedents under which procedural coordination becomes a significant component of IORCG.

Now, the genealogy of the legal and economic theories of contracting also sheds light on the rationale for IORCG choice and, in turn, the rationale for this research methodology. (Interested readers may refer to Walker and Pryke (2009) for a more detailed treatment of the evolution and expansion of the economic theory of contracts and methodological shift for incomplete contract (IC) analysis resulting from the failures of general equilibrium theory.) To summarize, the original contracting theory models were created for equilibrium studies and therefore, did not demonstrate how contracts worked in practice. Later there were calls from both economists and legal theorists to demonstrate, rather than assume, how contracts work in practice (Saussier, 2000). Furlotti (2007) observed that early economic theory's reliance on a highly unrealistic

depiction of real-world contracting resulted in disregard of the temporal dimension of contracts and the multidimensionality of incompleteness as a measure of contractual heterogeneity. This is why Furlotti (2007) deemed it important to demonstrate how contracts can perform similar functions to integrated structures using evidence from real-world contracts. By this, he was able to observe the general structure of contracts and the heterogeneity of IORCG design. He found that contracts span over non-negligible time periods and that incompleteness is conceptualized and operationalized (developed internally by an economic model) in different ways.

Due to the assumption that courts work in ‘informed, sophisticated and low cost ways’ (Williamson, 1983), under the traditional notion, contracts were not conceptualized as spanning over non-negligible time periods, with a potential need for adjustment. Because court adjudication is considered to be costly and imperfect, contracting parties try to shift the locus of decision-making and adjustment from the courts to the transactors. This is why contracts contain enforcement mechanisms. These enforcement features are also captured by the relational contracting concept which emphasizes the extra-contractual governance means complementary to those that have been specified by the formalized contract.

We used Furlotti’s (2007) observed general contractual content, heterogeneity, and sensitivity analysis of the antecedents influences to guide our review of the literature on the Frequency impacts from an OT perspective. We will present Furlotti’s (2007) propositions about contractual content and heterogeneity, in the next section and highlight the Frequency impacts identified.

Furlotti (2007) proposed that contracts consist of *transactional* and *procedural* elements. Parties use *transactional* elements to commit to undertaking specific performance in exchange for reciprocal undertakings of the counterparty. Therefore, the transactional part contains: commitments on tasks, resources, outputs and remuneration provisions. Remuneration provisions are regarded as a substantive aspect of contracts (the core, in effect) because through these, many goals, such as: sharing the quasi-rent (the difference between the value in use in which the investments are committed and the next best use (Klein et al., 1978)) of the collaboration, provision of incentives for adoption of efficient behaviour, risk allocation, and promotion of efficient adaptation and balance of different types of hazards are pursued. Where price adjustments are carried out during the life of the contract, the process is rarely formulaic, due to the zero-sum nature of such adjustments. Therefore, essentially, actual remuneration, rather than the provisions are subject to adaptation. Furlotti (2007) found support for the idea that Behavioural and Task Uncertainty affect flexibility in remuneration specification. Corresponding flexibility in specification of task obligations is required. Within the *procedural* elements Furlotti (2007) classified the rights and processes intended to serve purposes of: dynamic adaptation, integration, and preservation of a shared understanding. There is: *decision-making*, to discover the actions parties must undertake to produce or adjust the quasi-rent; *restraints* (rules) – to prescribe specific behaviour and ensure relationship predictability; rights underpinning *enforcement* of promises through payoff manipulation; and *monitoring*, which is instrumental to decision-making and enforcement. Goal statements and term definitions, which delineate the meaning shared by the parties, may also be included here.

4.1.4 Decision-Making

The requirement for decision-making is another consequence of non-negligible contract duration. Decision-making is also required because contract subjects may be so uncertain that performance

requirements cannot be defined *ex ante*, and substantial *ex post* planning mechanisms must be established. Furlotti (2007) observed various patterns of allocation of decision rights, namely: to either party unilaterally; to both parties, jointly or separately; and, also, to third parties (as is the case for construction projects). There were other observations of antecedents' influence on decision-making and its allocation. Joint decision-making for contractual adjustment usually results with greater contract rigidities, higher task uncertainty, and lower history of parties' past litigation. Contractual assignment of unilateral decision rights is more generous the less consequential those decisions for the party subject to them are. Parties to whom enough control rights are assigned can exercise actual control, regardless of asset ownership. Actual allocation of control is influenced by parties' respective bargaining power at the time of entering the agreement and fewer rights are assigned to the party with a conflict of interest. Finally, the assessment of decision rights to one party seems to be complementary with the simultaneous assignment of means of enforcement to that party. Furlotti (2007) did not comment on the sensitivity of decision-making elements to Frequency, and our analysis did not seek to measure decision-making elements nor detect such Frequency impacts in the literature reviewed.

Enforcement

As mentioned previously, contractual Enforcement mechanisms (self-help) serve to reduce reliance on enforcement by court adjudication. Furlotti (2007) concluded the following: i) the probability of non-performance can be reduced through greater contractual formalization; ii) where formalization is not feasible, assignment of certain decision rights or hostages (such as construction performance bonds) may be used to deter non-performance; iii) as dependence of one party upon another increases, so does the intensity of either form of enforcement. Second-party termination rights are another type of Enforcement mechanism proposed by Klein and Leffler (1981), who argued that the existence of a flow of quasi-rent, coupled with the threat of termination, is sufficient to assure performance if the parties perform repeat transactions. This can be regarded as a forward-looking ('Shadow of the Future') perspective of Frequency.

Lumineau and Malhotra (2011) explained how deadlined vs open-ended contracts might also be expected to affect IORCG choice. They stated that parties with short-term contracts may envision a short Shadow of the Future and may choose to rely more extensively on contractual provisions (Poppo et al., 2008). In our review, Shadow of the Future (expected future interactions) was measured by taking note of special arrangements that increase the likelihood of cooperation and reciprocity in future interactions. According to Vanneste and Puranam (2010), expected future interactions may lead to less reliance on contractual detail for ensuring cooperation (Axelrod, 2006; Heide and Miner, 1992), however, longer futures may make it worth investing more heavily in additional safeguards (Williamson, 1985). Thus we noted that the literature had not yet decided on the aggregate effect of expected future interactions. Three items were used to measure Shadow of the Future. One item asked: 'To what extent future actions were expected at the time of contract execution?' The extreme categories of the five-point answer scale were: 'not likely' and 'very likely'. The aim of the second item was to detect the existence of special arrangements such as Framework agreements. The third item asked whether the contract in question specified a pre-defined length of time or whether it described an open-ended relationship (Reuer and Ariño, 2007).

Rules and Restraints

Furlotti (2007) cites Klein and Murphy (1988) who refer to restraints as ‘a series of practices that are commonly referred to as such’. He also cites Lafontaine and Slade (2005) generic definition as ‘any restriction that is imposed by one member (...) on the other member of the relationship.’ In relational contracts, the prescription of specific behaviour through rules increases with the level of externalities. Overall, the role of rules in contractual governance has been the focus of very little investigation. Yet, the evidence available indicates their use in contracts is influenced by contextual factors that deserve further analysis. Therefore, this research did not seek to detect Frequency impacts on the Rules and Restraints found in the construction IOR contracts reviewed.

Monitoring

Furlotti (2007) is of the view that Monitoring may be considered as an integral part of the enforcement apparatus. Agency Theory (the branch of financial economics that looks at conflicts of interest between people with different interests in the same assets), views Monitoring as a cure to conflicts of interests. However, Monitoring may be useful to prevent non-performance that is simply accidental or caused by insufficient skills. Thus, there are numerous reasons to analyze it as a process not entirely explained by the same factors as Enforcement. In sum, several of the authors reviewed see a role for Monitoring in contracting. Empirical evidence confirms that Monitoring is a relevant process addressed by relational contracts. Furlotti (2007) felt that the little evidence supported hypotheses based on Agency Theory and ICT. Nevertheless, the findings suggest that enhanced supervision and monitoring by principals are required when financial adversities render mistakes more costly and when short track records make it more difficult to assess counterparties’ revenues at the time of financing of venture capital contracts (Arruñada et al., 2001). Ryall and Sampson (2006) also provided further empirical evidence that Frequency (in the form of prior deal experience) positively and significantly affects the level of Monitoring. In this light, we depended on Ryall and Sampson (2009) for our measure of the extent of Monitoring provided for in the contracts under review. The categories of the seven-point answer scale, increasing in the extent of Monitoring provided for were: i) Project reviews ‘required’ (including documentation development and construction progress) ii) reviews of the completed works (including documentation development and site work) only required iii) discretionary reviews of production information are to be permitted iv) Timing of reviews specified v) Content of reviews specified vi) Physical Audits of completed work required v) the principal may reject the end products of the contractor if they materially fail to meet requirements.

4.1.5 Contract Duration and the Multidimensionality of Contractual Completeness

Furlotti (2007) organized the contract dimensions, according to: Duration, Complexity, Contingency Planning, and Specificity.

Duration

Economists and business scholars observed that the heterogeneity of contracts could be measured in terms of Duration. Therefore, it is a dimension on which antecedents’ canonical TCE dimensions of transactions effects should be tested. Duration is recognized as a fundamental design variable for IORCG under conditions of transaction-specific investment, and has been investigated empirically. The study results indicate that in some contexts, parties use Duration as

a safeguarding device to protect reliance (the interest of a party to a breached contract in being compensated for detriments suffered (as expenses incurred) in reliance on the agreement) in a variety of contexts. Duration benefits (savings on bargaining costs of repeat negotiations) must be traded off against the associated costs (potential for maladaptation). The effectiveness of Duration is enhanced by simultaneous use of mechanisms that define admissible dimensions for adjustment. In other situations, such as manufacturing, long-term contracting is less well-suited to project-specific investment.

The Multidimensionality of Contractual Completeness

In recalling the genealogy of the economic theory of ICs and reflecting on positive economic theorists' attempts to model Incompleteness, Furlotti (2007) reminded that incompleteness should be understood as 'the possibility to improve efficiency ex post'. Endogenizing (internally developing an economic model parameter) Incompleteness in this way prompted a stream of research deploying a variety of denominations and operationalizations for Incompleteness constructs. It then became apparent that all the virtues of the contractual ideal type could not be achieved by increasing only one specific contract dimension. Also, as a result of the review being restricted to drawing conclusions about dimensions on which empirical investigation had actually been conducted, Furlotti (2007) regrouped the dimensions often encountered and referred to as Incompleteness, under three labels, namely: Complexity, Contingency Planning and Ambiguity/Specificity. These correspond to three contractual strategies that are said to be effective in fulfilling the competing requirements of reducing risk of contractual non-performance and ensuring the possibility of harmonious ex post adaptation.

Complexity (CD)

The reasoning behind Complexity as a measure of Completeness is based on the view that real-world contracts approach the complete archetype when there is higher language stringency and greater exertion in foreclosing possibilities of misbehaviour. Therefore, the studies regarded more complex contracts as being longer, including a higher number of clauses, and providing for larger arrays of enforcement mechanisms. Thus the evidence on Complexity is in the form of studies that empirically investigated relationships between Complexity and transaction strategic importance; and between Complexity and contractual hazards created by cooperative venture Size and Frequency in inter-firm strategic alliances, international joint ventures, information services, dyadic alliances, IT and biotech R&D, and IT products and accompanying services contexts. After reviewing this evidence, Furlotti (2007) concluded that: the risk of project hold-up is better captured by Size, which proves to be the most significant antecedent of Complexity; however, he found no strong indications that more efficient contracts ought to be more complex as Frequency increases or when there are greater contractual hazards.

Furlotti (2007) made no observations of the impact of Frequency on CD, but outlined measurement approaches encountered in the studies reviewed. For the contract set under study, number and stringency for the CD can be evaluated, using the Walker and Pryke (2009) operationalization, which is based on the Parkhe (1993) 'contractual safeguards' operationalization. This is an assessment of strength of explicit contractual opportunism deterrents. Parkhe (1993) examines contracts for the presence of provisions embodying the specific contractual enforcement apparatus for the type of agreement in question. Once identified in the contract set, with the help of practitioners, the provisions can be ranked in order of

‘increasing stringency’ to facilitate a stringency score assignment. Next, these scores can be summarized into an ‘index of deterrents’ (IOD). For each contract, an IOD can be determined by arranging safeguards in order of increasing stringency and assigning each its corresponding value. e.g. the first-ranked safeguard would be assigned a value of 1, the third – 3, etc. The composite IOD would then be computed as $\sum(\text{number of safeguard used})/\sum(\text{number value of all possible safeguards})$. Higher IOD values are expected for large, important contracts with heightened perceptions of opportunistic proclivities.

Contingency Planning (CPD)

Contingency Planning measures the intensity of use of one particular strategy to achieve efficient adaptation, e.g. it can measure the degree to which parties use a strategy of developing explicit response rules for specific classes of events. The general consensus is that parties generally resort to this strategy, as *ex ante* conflicts of interest increase and as costs of specifying contingencies decreases (Furlotti, 2007). Using the Mayer and Bercovitz (2003) evidence, Argyres et al. (2007) find that CP is positively affected by prior relationships between the parties. While the result is open to the interpretation that a history of frictions advises the adoption of greater safeguards under the form of stricter CP, Argyres et al. (2007) subscribe to the view that repeat interactions allow the partners to develop relation-specific routines, and lower the cost and effort of explicitly planning for contingencies. Mayer and Argyres (2004) also favour this interpretation.

Respondents were expected to grade contracts on: ‘degree to which parties develop explicit response rules for specific classes of events’, using the Mayer and Bercovitz (2008) three-point CP scale:

- 0 if there is no CP for the project
- 1 if there is CP to accommodate ‘any’ kind of change
- 2 if there is more specific and detailed CP

Ambiguity and Specificity (ASD)

Introducing Ambiguity (broadly stating requirements, without restricting parties to specific actions, i.e. failing to specify verifiable obligations of parties) is a common strategy for increasing the adaptability of a contract. For example, in the construction industry, fixed price contracts can be arranged in increasing order of Specification Ambiguity as follows: fixed design, scope design, and cardinal points’ (Turner, 2004). Furlotti (2007) reviewed evidence for this relevant dimension gathered from empirical studies that investigate ‘contract specificity’ or ‘contract detail’ because the studies do not generally address the opposite issue of ‘Ambiguity’. In sum, the findings indicated that Contract Specificity decreases with Uncertainty and increases with behavioural hazards. Also, in certain settings, the existence of relational reinforcement mechanisms also favoured greater contractual detail (Furlotti, 2007).

The Ryall and Sampson (2006) database, already mentioned for its implications for measuring Monitoring, was cited by Furlotti (2007) to illustrate that contracts can be more detailed when organizations have prior detail experience, and have engaged in prior deals with the same partner. The implication is that there is a learning effect and the capacity to draft detailed contracts increases with experience. Argyres et al. (2007) also find evidence of complementarity

between task description detail and CP due to learning spillovers from prior relationships. Corts and Singh (2004) was regarded as evidence that contracts based on more ambiguous term specification (in that they fail to specify verifiable obligations of the parties) are increasingly opted for when previous experience with the same partner assuages moral hazard fears.

To operationalize ASD, we depended on the procurement route indicated by the respondent for the project in question. Similar to Crocker and Reynolds (1993), we consider the more fully-specified contracts to be procured via the traditional route, using fixed price contracts and the least fully-specified contracts to be the fee-based (cost reimbursable) contracts

5 Conclusion and Further Research

This study provides insight into the motivation for and design of IORCG mechanisms based on primitive transaction/project characteristics. The question of how the Frequency primitive project characteristic impacts IORCG design has, surprisingly, received relatively less attention in prior research, in comparison to Asset Specificity and Uncertainty, despite it being identified alongside them as one of the principal TCE dimensions for characterizing transactions (Williamson, 1985).

Our focus on the Frequency of trade between organizations differs from prior studies in that we do not limit ourselves to evidence of relationships and influences put forward by any specific theoretical perspective. Rather, our study represents a consolidation of different theoretical perspectives on IORs to develop a comprehensive framework for assessing the contribution of prior transaction history on general IOR governance mechanism design. Our findings indicate that the IT and IT Services, High Technology, and Biotechnology fields are leading the charge on investigation into the Frequency impacts. As this study applies the general findings and approaches uncovered from our review to the design of IORCG mechanisms in the UK construction industry, it will add specific dimension here.

Our findings also indicate that initially, the general consensus was that the relationship between IORCG mechanisms and Frequency was moderated by the trust, generated from repeated interactions between the same trading partners. This would imply that that IORCG would become less complex, (as the need for control is reduced) with increased levels of experience with the same transaction partner. However, as the evidence began to indicate otherwise, alternative explanations were put forward, such as the incorporation of past experience and lessons learned into newer contracts (learning spillovers). There was support for both substitutive and complementary effects of partnering experience that run through different paths. The focus then shifted toward disentangling the trust effect from other consequences of relationship history, such as learning spillovers. The most recent suggestion was for a ‘trust first, learn later’ pattern.

Despite its contributions, there were some limitations. For example, despite identifying a number of features and mechanisms of IORCG, we were unable to find studies providing evidence to indicate the sensitivities of each to Frequency. Specifically, our study made no observation of Frequency impacts on decision-making and rules and restraints. Also, review of impacts on the coordination function, and for monitoring were also quite limited. Therefore, given the significance of these dimensions, in addition to the dearth of research about these issues, we feel

that these missing dimensional sensitivities is an area that warrants further investigation and analysis.

We also noted that the literature was still undecided on the aggregate impact of expected future interactions, though there is some speculation about the effects of open- vs close-ended contracts. For the most part, the notion of Frequency here was basically, an analysis of the ‘Shadow of the Past’, and therefore, we recommend that future research strive for a more balanced view that would incorporate the ‘Shadow of the Future’.

Some more specific measures for construction industry subsectors could also be developed. For the measure of Complexity, we were largely dependent on Parkhe’s (1993) operationalization. Specifically, a measure of contract Complexity, that incorporated input from a wide variety of practitioners to develop a similar IOD for a specific subsector would enable greater insight into the Frequency impacts for specific construction subsectors. Also, we used a rather simple measure for the Ambiguity/Specificity Dimension. Our recommendation is for future research to draw inspiration from Ryall and Sampson (2009) to develop frequency and cross-frequency tables presenting incidence of occurrence and co-occurrence of terms across contracts in a set. Such a structural presentation would provide the benchmark, and thus, the upper bound for ASD. In this way, a more objective procedure for checking contracts against this descriptive structure would enable determination of how ‘fully-specified are contracts within particular subsets. Contractual content can be measured by examining the number of terms within each broad category of variance.

Finally the validity of our methodology may be subject to debate. Our use of survey data may cause concerns about potential biases, e.g. common method biases. However our use of more objective indicators for many of our constructs should alleviate some of these concerns. The cross-sectional approach to data acquisition may cause some concerns about recall bias and may constrain our ability to examine dynamics between prior relationships and IORCG mechanism design. Use of objective indicators should also be helpful in this regard. Future research recommendations are for longitudinal studies, which would allow more in-detailed and dynamic examination of Frequency and prior relationships and their impacts on IORCG.

Despite these limitations, we believe that our results have significant implications for those involved in designing IORCG mechanisms, who need relevant knowledge to make design choices. They will be able to design suitable IORCG mechanisms to address hazards associated with the primitive project characteristics (Frequency, in particular) with which they are faced. They will also be able to conduct marginal analysis using the IORCG mechanism measures. Given the continuing growth of IORs in the construction industry, the need for guidance on designing effective control structures will only increase in importance.

APPENDIX

Table 1 Empirical research on Frequency Impacts on Interorganizational Relationship Contract Governance Design

YEAR	INDUSTRY	PAPER AUTHORS	SUMMARY OF PURPOSE OF STUDY	IMPACT OF FREQUENCY ON IORCG (SUBSTITUTE OR COMPLEMENT)?	CONSISTENT WITH TRUST, LEARNING EFFECTS, INFORMAL OR SOCIAL CONTROL?	PART OF CONTRACT Affected
2011	Animated film industry	Lumineau, Frechet, and Puthod	Longitudinal study of alliance contracting. Discussion of how contracting and learning processes are related. Analysis of the role of the contractual process in supporting organizational learning.	Frequency encourages parties to learn about: each other, transaction features, and the contracting process.	In addition to Experiential learning (trial-and-error learning or learning-by doing: making meaning from direct experience), there are: vicarious, and inferential learning mechanisms from repeated interactions.	No linear relationship between contractual details and experience was observed (as was the case for Vanneste and Puranam).
November-December, 2010	Buyers and Suppliers of IT products and services. IT Transactions range from: Routine commodities to highly customized and specialized development projects, which usually require relationship-specific investments, high levels of integration and mutual coordination.	Dekker & van den Abbeele	Analysis of transactions between buyers and suppliers to determine how partner search processes and prior exchange experiences impact firms' ability to design control structures for new inter-firm interactions.	BOTH COMPLEMENT & SUBSTITUTE: Partner search and prior experience facilitate learning and control design, but reduces the need for control and the intensity of the partner search process (need for new information is reduced) for new transactions.	Prior experiences increase trust and provide first-hand partner experience. Prior experience with focal partner has a negative direct effect on use of control mechanisms to manage interfirm transactions.	Control mechanisms: (Outcome Control; Behaviour Control)
March, 2010 June, 1998	Biotechnology Research Agreements	Lerner and Malmendier	Analyze how contractibility affects design.	Alliances negotiated at the earlier stages allocate fewer control rights to R&D firms	Learning	Procedural/Control: Effort Incentives Complementarity between enforcement mechanisms and wider decision rights Procedural: Decision-Making
January,	IT Procurement by Dutch	Vanneste &	Analysis of conditions	COMPLEMENT: Learning	Learning Effects	Frequency: Technical

YEAR	INDUSTRY	PAPER AUTHORS	SUMMARY OF PURPOSE OF STUDY	IMPACT OF FREQUENCY ON IORCG (SUBSTITUTE OR COMPLEMENT)?	CONSISTENT WITH TRUST, LEARNING EFFECTS, INFORMAL OR SOCIAL CONTROL?	PART OF CONTRACT Affected
2010	small- and medium-sized enterprises (SMEs)	Puranam	under which learning effect is most likely to manifest itself.	effect is stronger for technical, than for legal detail; and is stronger for firms with IT expertise than for firms without such expertise		Provisions become more detailed. Legal Provisions do not become more detailed. The learning effect is stronger for technical provisions than for legal provisions, and for transactors with at least some in-house IT expertise.
June, 2009	Joint Technology Development in Telecommunications and Microelectronics (High Technology Sector)	Ryall & Sampson	Investigation of the extent to which firms substitute relational for formal mechanisms in the presence of repeated interactions (Empirical comparison of contract terms in 52 contracts)	COMPLEMENT (between formal and relational contracts): Prior deal experience affects positively, and significantly, the level of monitoring. The firms' contracts are more detailed and more likely to include penalties when it engages in frequent deals	Informal/Social Control (Relational Capabilities) A learning effect for Specificity – increased capacity to draft detailed contracts with increasing experience.	Transactional: Enforcement Procedural; Ambiguity/Specificity Frequency: Penalties more likely with increased interaction.
2008	Sequential exploratory (purpose was to evaluate new technological opportunities through upstream activities, such as: fundamental research, experimenting, and testing) R&D alliances between	Faems et al.	Case study of two sequential alliances between the same pair of R&D firms. 1 st Alliance: Exploration of feasibility of side shooter head (SSH) for printing applications	Disentangling of how: (1) contracts with a similar degree, but different nature of formalization (narrow vs broad) trigger different types of trust dynamics at operational and managerial levels. (2) trust dynamics and	Contract designs differed in the way that monitoring, task division, and information flows were defined, but were the same regarding the juridical clauses regulating partner	Provisions for Monitoring, task division, and information flows

Contract administration

Standard Forms of Contract Selection Criteria: A Qualitative Analysis of the Western Australian Construction Industry

Andrew Whyte¹ and Erin Macpherson¹

¹ Dept. of Civil Engineering,
Curtin University, Perth, WA,
Australia

Email: andrew.whyte@curtin.edu.au

Abstract:

Opportunities exist for a new structured decision-making criteria guide, towards selection of the most appropriate standard form of contract, in a given environment, for the West Australian (WA) civil-engineering/construction industry; the work presented describes decisions required to choose an effective standard form of contract (from a wide array of options) and the factors that influence these decisions. Secondary research identified a lack of structured guidance available locally, paving the way towards primary research, in conjunction with stakeholders in the Australian engineering construction industry, in the development of a new guidance tool. Data collected, analysed as part of a qualitative research methodology, provided the findings to develop subsequently a practical, objective, and structured standard form of contract selection guide for use within the local construction industry. The decision flow chart developed as part of this research is expected to improve the speed and accuracy in the choice of which standard form of contract is most suitable from the wide range of available options. This guide may also serve as a contract training aid for graduate civil-engineers involved in procurement activities in the construction industry.

Keywords:

contract, decision-making, Western-Australia, civil-engineering/construction

1 Introduction

This study explores contract alternatives in the West Australian (WA) Civil-Engineering/Construction Industry, with a key focus on the decisions leading to the choice of which standard form of contract is most suitable for a given Australian development project.

The purpose of a contract is essentially to ensure that what is agreed will in fact be carried out by the relative parties. In essence a contract acts as a measure to mitigate risk by outlining the requirements of the parties. However, the very existence of a contract cannot guarantee the omission of risk. An effective contract is one that outlines the responsibilities of the parties in a clear and precise manner. While this remains the

constant goal for industry, in reality this is very difficult to achieve due to respective stakeholders' varying interpretations of clauses.

Industry strives for continued improvement, that is, the minimisation of interpretations and the protection of the interests of the respective parties. A large number of alternative (WA) standard forms of contract have been developed to address this concern; however this in turn adds to the complexity of the contract choices and the decision process due to the sheer number of standard form of contract options available. Western Australian (WA) professionals identified a number of contractual concerns, particularly significant Liquidated Damages, associated with projects conducted in their unique home-state (WA is comparable in size to Western Europe, has a population of 2.3 million, and the world's most isolated mainland city, Perth) (ACA, 2008).

In order to make a decision as to which standard form of contract to use, experienced contract engineers often currently follow an innate, and largely subjective, decision process. Firstly a decision must be made as to which procurement strategy is likely to prove most suitable. Secondly, an appropriate tender process to engage contractors and consultants needs to be selected. A decision also needs to be made as to which type of contract will appropriately meet the needs of the chosen procurement strategy and finally which standard form of contract will best serve the needs of the project. Figure 1 outlines these decision relationships as defined by this research (where column four represents the range of potential standard forms of contract available for (West) Australian construction and civil-engineering activities.

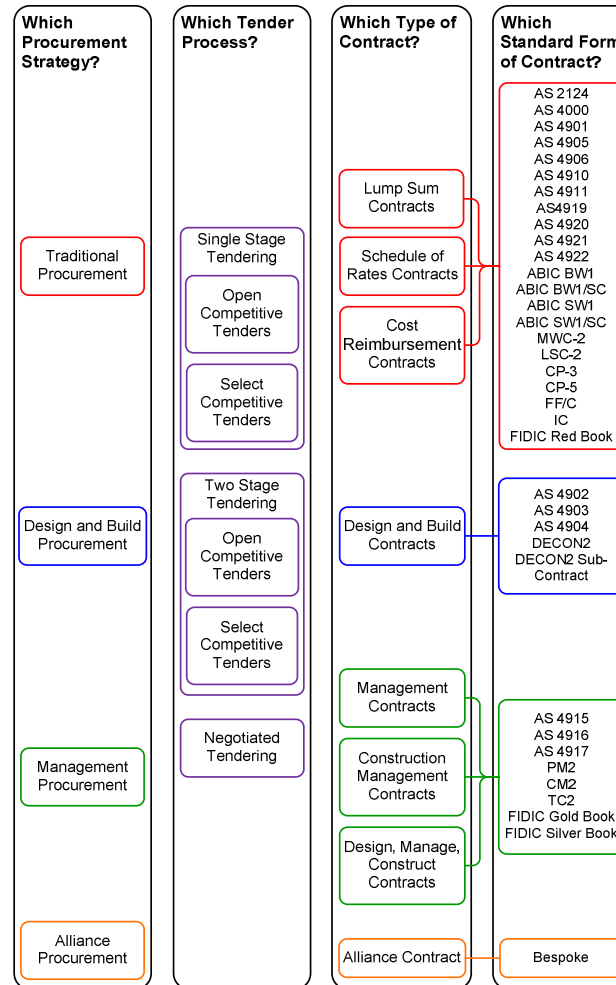

Figure 1: Contract Decision Relationships for Western Australia

This research looks to formalise this somewhat innate, subjective process by developing a structured, objective decision making guide towards the best alternative form of contract in a given environment. The research draws on a variety of sources, collating this information to provide a comprehensive overview of not only the factors considered in order to make an appropriate decision, but also the final product and its relative advantages and limitations.

1.1 Research Problem: Contract Choice in WA

The primary problem within the WA engineering construction industry which has motivated this research is the markedly large number of standard forms of contracts available to contract decision makers, coupled with the lack of independent guidance on which standard form is most suitable. The high number of choices available and the number of decisions that are needed to be made makes the decision process a difficult task requiring considerable time and therefore monetary investment in order to select an effective standard form of contract. Without a clear contract selection guide it is easy to neglect the full range of factors given the number of considerations that must be taken into account. Also, as a result of the complexity of this decision the task is generally reserved for experienced engineers who must draw on their years of individual experience in order to ensure a comprehensive consideration (which remains a personalised and subjective consideration) of the relevant factors.

This problem can be seen to offer three opportunities for improvement:

Firstly, to improve the efficiency of the contract decision making process;

Secondly, to improve the effectiveness and objectivity of the contract decision making process; and,

Thirdly, to pass on contract knowledge in such a way as to allow less experienced engineers to take on more responsibility in making contract decisions.

These opportunities would be best met by a structured approach to contract form selection. A need therefore exists within the WA civil engineering construction industry for a structured approach to making contract decisions.

1.2 Purpose of the Research: Decision Making Guidance

The purpose of this qualitative study is to gain a better understanding of how contract decisions are made within the Australian construction industry and use this understanding to develop a new structured contract selection guide by way of a decision flow chart for West Australian consultants to advise clients of the most suitable standard form of contract. This decision flow chart will look to improve the efficiency with which contract decisions are made while improving the probability of the most suitable contract being implemented for a given project.

2 Background: Contract Selection in WA

Civil engineering consultants are often asked to advise unknowledgeable clients on which standard form of contract to use for construction projects. It is important to choose an appropriate contract which balances the project parameters and allocates risk appropriately in order to avoid poor quality of construction, time and cost overruns, and reduce the likelihood of claims and litigation (Rwelamila, 2007). A compromise is also often required between conflicting project parameters such as cost, time and quality (Turner, 1997; Cox, 1999). For example, high product quality is likely to be achievable at a higher cost or longer timeline (Chua 2006). Similarly, in order to achieve shorter project programs than thought to be ideal, product quality may be reduced, or increased costs may be experienced (Chua 2006). The challenge of successful consultants is to find a balance between these priorities through suitable contracts (Wang 1996).

The contract decision is one which is very complex, requiring careful consideration of a number of different variables in order to reach a final decision (Rwelamila, 2007; Chua 2006; Wang 1996; Luu, 2003). It is widely accepted that the success of a contract, and therefore a project, is dependent on the appropriateness of the contract, being objectively assessed against the characteristics of the project and the project priorities, on an individual basis (Rwelamila, 2007; Chua 2006; Wang 1996; Oyetunji 2006). With no structured approach to contract decision making, consultants run the risk of investing vast amounts of time into making correct contract decisions, or, alternatively, they may rush the decision, or neglect to consider important variables resulting in a less than optimal contract being implemented.

A number of studies (Love, 1998; Wong, 1995; Wang 1996; Skitmore, 1988; Oyetunji 2006) have sought to develop a structured decision procedure for particular aspects of

the contract decision making process. However, it might be suggested that these influential studies seek not to attempt to offer a *complete* solution to the contract decision; concentrating upon either procurement strategy or the type of contract.

This project initially sought to identify the variables deemed most important to the decision making process through a secondary research methodology. This research identified a total of fifty-three variables that influence the contract decision. Of these, thirteen variables were mentioned by a significant number of researchers, and are therefore considered to most greatly influence the choice of form of contract. This research looked to develop a new means to measure the significance (or weighting) of these 'project priority' variables against the 'project characteristic' variables for various situations (looking at how the project priorities in WA influence the contract decision for different types of projects).

3 Methodology

The nature of the research question played a significant role in determining the most appropriate research methodology. It was considered that enquiries into how contract decisions are made to improve suitability and efficiency were best achieved by the use of the qualitative method of research. This method allowed the contract decision process to be investigated in terms of understanding the circumstances in which study participants address issues in decision-making (Creswell, 2007).

Pilot study data collection was undertaken in the form of six semi-structured interviews with procurement and contract professionals within the engineering industry. Interview participants were identified using 'purposeful sampling' with a view for 'maximal variation' (Creswell, 2007). On this basis participants company profiles varied in size, nature (client/consultant/contractor) and sector (public/private). All participants were senior personnel with extensive knowledge on contract and procurement practices.

4 Discussion of Results

4.1 Semi-Structured Interviews

The interviews conducted as part of a primary research methodology provided a means to measure the importance of variables identified as part of the secondary research literature review. These interviews indicated a high correlation between the factors considered by industry professionals within the Australian construction industry and those identified through the literature review. However, a number of (widely international) factors, considered influential to the standard form of contract decision by this research were neglected by the participants of this study. The reason for these omissions was likely due to the limitations of size; the sample size was of six participants, limiting perhaps variation measurement across the WA construction industry. It is for this reason that the standard forms of contract, and associated decision variables, explicitly mentioned in these interviews were likely to be limited to those administered by an engineer and used within the WA engineering construction industry. As such standard forms of contract developed by *Standards Australia* were highlighted in this study.

The interviews conducted as part of this research also raised the issues of client-contractor relationships and difficulties in changing the industry ethos. The relationship between the client and the contractor impacts on every factor taken into consideration in the decision process and is therefore fundamental to the success of the project. While a contract defines the relationship between the parties in terms of liabilities and responsibilities it cannot define the attitudes of the parties on which these will be based. Therefore in order to achieve positive project outcomes in terms of low costs, short schedules and high quality it is important that both the client and contractors conduct themselves in a manner that encourages respect and co-operation between the parties. The benefits of such are expected to extend beyond the client in terms of improved value for money for the project to the consultants and contractors as a result of an increased workload (and therefore profits) brought about by a positive industry reputation and repeat work with the client.

The tendency within the West Australian construction industry to over simplify construction administration without due consideration to the increased legal environment in which they operate was also raised amongst participants. The increased emphasis on reducing the project schedule (time constraints) was cited as the most likely reason for this industry culture. Similarly, time constraints and lack of familiarity with all alternative options was indicated by participants as the most likely reason for implementing a contract out of familiarity (because it had been used on a similar project) without due consideration to all the relevant factors. On this basis, the use of a selection guide, such as the one developed as part of this research, is likely to eliminate the trade off between speed and suitability by facilitating an accelerated contract decision (and therefore project start) while ensuring a suitable contract is selected.

4.2 Key Decision Factors

This research identified a total of 28 factors as influential in the contract decision process. Of these 28 factors a number of factors influence more than one decision as summarised in Table 1 below.

Table 1: Key Decision Factors

No	Factor	Procurement Strategy	Type of Contract	Tender Process	Form of Contract	TOTAL
1	Schedule/timing	•	•	•		3
2	Minimum cost	•	•	•		3
3	Cost certainty	•	•			2
4	Complexity	•	•	•	•	4
5	Nature	•	•		•	3
6	Expected cost/value	•	•	•	•	4
7	Scope	•	•			2
8	Size	•	•			2
9	In-house capability	•	•			2
10	Quality	•	•	•		3
11	Allocation of risk/responsibilities	•	•		•	3
12	Market conditions		•	•		2
13	Flexibility	•	•			2
14	Level of competition	•	•	•		3
15	Time certainty	•				1
16	Control over sub-contractors	•	•		•	3
17	How well defined scope is	•	•		•	3
18	Evidence of transparency			•		1
19	Evidence of competition			•		1
20	Number of vendors able to supply goods/services	•		•		2
21	Dispute avoidance	•				1
22	Project administrator				•	1
23	Location				•	1
24	Funding				•	1
25	Procurement strategy leads to difficulty in evaluating tenders			•		1
26	Domestic/commercial				•	1
27	Separable portions required				•	1
28	Client profile				•	1
	TOTAL	18	16	11	12	

It can be seen that a total of 18 factors impact the choice of procurement strategy, 16 factors influence the choice of the type of contract, 11 factors influence the decision of which tender process will be used and 12 factors impact the decision as to which standard form of contract is most suitable. The research also indicated that these factors

were unable to be assigned a specific weighting given their interdependence on one another and the priorities of the individual project.

4.3 Standard Form of Contract Decision Flow Chart

The factors identified through this qualitative research methodology as influential to the standard form of contract decision, outlined above in Table 1, were used to develop a new series of eight related decision flow charts (alongside factor interrelationship implications, notwithstanding the recommendations discussion below) to aid in the selection of a suitable standard form of contract for Australian civil engineering construction projects¹. Figure 2 shows a representative sample of the finalised decision flow chart developed as part of this research. The flow chart directs the user to complementary pages of the final research report (*go-to page 92*, and the like) where a final decision suggestion arises from a yes/no series of project status questions within the model; a number of definitions are also made available within the final report to assist the user to identify/objectify respective yes/no onward responses. This model flow chart specifically applies to the factors influencing the choice of procurement strategy, as the first step in the four stage process (refer to Figure 1).

The collective decision flow chart(s) developed as a result of this research can be argued to have a number of significant benefits to the West Australian construction industry. Firstly it will save time by reducing the number of hours required by contract engineers to make a standard form of contract decision. It will also reduce, if not eliminate, the requirement for legal consultation therefore reducing the time required for negotiations between clients and contractors or consultants. This research will also enable contract knowledge to be passed on to new contract staff more efficiently and comprehensively. The structured selection guide is also expected to improve corporate memory by reducing the risk of contract and procurement knowledge being lost when experienced employees leave the company. The structured contract selection guide will also allow less experienced contract engineers to take a more active role in the contract selection process, in turn reducing the involvement of more experienced engineers and therefore allowing these experienced engineers to be available to perform more advanced tasks. A structured contract selection guide ensures all important variables are considered for every project leading to the most suitable contract selection. The implementation of effective contracts leads to improved client contractor relationships and reduced litigation. Given the direct relationship between time and money, the time savings brought about by a structured selection guide will translate to significant cost savings. The cost of legal consultation in developing a bespoke contract is also a considerable one in contract management and the reduction, or negation of this requirement is expected to be significant. Improved corporate knowledge is expected to reduce costs by maximising the efficiency of experienced, more costly, engineers. Litigation is an expensive by-product of ineffective contracts due to the exorbitant cost of lawyers and legal fees. Therefore the reduced litigation as a result of suitable contract selection is expected to lead to significant cost savings.

¹ Final, full (unpublished) Decision Making Guide Report is available from Civil Engineering, Curtin University

Figure 2: Decision Flow Chart – Procurement Strategy

5 Conclusion

This qualitative research focused on the decisions that are required to be made in order to select an effective standard form of contract and the factors that influence these decisions. Four key components to the form of contract decision process were identified. These components required decisions to be made between four identified procurement strategy options, five tender process options (including single stage and two-stage tendering), eight types of contract and over 48 standard forms of contract that are available within Australia. A total of 28 factors were identified as influential in the form of contract decision process which were unable to be assigned a specific weighting given their interdependence on one another and the priorities of the individual project.

The standard form of contract decision flow chart(s) developed as part of this pilot study research is expected to improve the speed and accuracy with which the decision of which standard form of contract to use is made. This guide is argued to also serve as a contract training aid for graduate engineers within the construction industry.

6 Recommendations

Due to the time constraints of this research the sample size was limited to six participants with prominent industry professionals. In order to improve the accuracy and applicability of the decision flow chart developed as part of this research it is recommended that additional primary research be conducted for a larger, and more diverse sample of participants. Results would best be achieved by conducting further structured interviews with contract and procurement professionals across a broader industry profile (for both domestic and non-domestic markets) and from companies defined within a small & medium enterprise (SME) category. Participants with backgrounds beyond civil-engineering encompassing development, building and architecture would also be seen as beneficial.

It is also recommended that further research be conducted to establish a more definite weighting system for the factors identified in this research; these factors were found to be heavily dependent on (historical) experience and as a result further validation by case-study is recommended. This would enable participants to directly relate these factors to a tangible situation. Benefits could also be seen from investigating processes and factors to improve client-contractor relationships within a contractual framework. This is expected to positively impact on the outcomes of the project in terms of costs, time and quality while improving contractor profits.

Integrated Project Delivery: A Hidden Thorn of Decreased Cash Flow for the participants

J. Mark Taylor, Ph.D., JD¹ and Darren Olsen, JD¹

¹McWhorter School of Building Science
Auburn University, Auburn, Alabama
United States of America

Email: taylorjt@auburn.edu, dao0002@auburn.edu

Abstract:

Integrated project delivery, or IPD, is a relatively new form of project delivery, but its principles have been around for as long as building has been documented. In the early days of historical construction, the project was entrusted to a single person known as the master builder. This master builder was responsible for both the design and construction of the project; thereby providing the owner, or project sponsor, with a single point of contact in line with what we now refer to as IPD. As the design profession matured into a profession separate from the building process, the building industry got away from the concept of master builder and owner's found it convenient to treat the two aspects of the project contractually distinct. In the more recent history of building, more and more information has been made available on the advantages of various forms of a collaborative building process which has led to the utilization of IPD.

A recent development adding to the "collaborative" discussion is that of building information modelling (BIM). BIM is becoming a popular tool offering many benefits to those utilizing the technology along with a BIM based building process. While many use only a portion of BIM for their personal needs on a project (e.g., an owner utilizing BIM for purposes of visualization or marketing; an architect utilizing BIM for developing schedules; or a general contractor utilizing BIM for clash detection), a BIM based building process, by nature, helps facilitate a collaborative approach to building. As collaborative efforts become more commonplace, building owners and all participants in the process need to be aware of how IPD is different from processes they may be more familiar with, and what should be expected from an IPD project.

On most projects an area of particular concern to the general contractor is that of cash flow. As an industry, general contractors are undercapitalized, work on relatively thin margins, deal in a cyclical market, and work with a retainage system that does not fully pay for their efforts until a project is complete. These factors, in combination, bring about a cash flow situation that is the downfall of many contractors. Poor cash flow is generally referred to as the number one cause of construction company failure in the U.S.

The purpose of this research is to look at a typical construction project and how the IPD delivery method can affect the cash flow cycle. A case study approach will be utilized

to illustrate the difference between the cash flow on a traditional commercial construction project in the U.S. versus a similar project in scope utilizing an IPD approach. While contract language can be utilized to minimize a change in the project cash flow cycle, this is an often overlooked detail during contract negotiations. The overall objective of this study is to clearly point out the differences in cash flow resulting from a traditional delivery method versus an IPD contract so that all participants in the project will understand how the cash flow cycle is changed and how it affects your profitability. With this knowledge as a basis, the participants can structure the contract language to best protect their interests. The paper will also provide a brief historical context on IPD.

1 Introduction

Integrated project delivery (IPD) has been a frequent topic of discussion in the AEC industry for the past few years. Many consider this a continuation of on-going discussions about exploring different and better ways of working together without truly adding to the effort; while others look upon IPD as a significant shift in the way the AEC industry operates. Those with the former attitude would point to the fact that over the past fifty years or so the AEC industry has seen the introduction of design build, construction management, construction management at risk, prime contractors, value engineering, collaboration, etc. All of which aim to have the pertinent parties - the architects, engineers and contractors - work more closely together and work more closely together earlier in the delivery process. Many refer to the use of IPD that is not a true shift as an IPDish project. As discussed in the next section, an IPDish project is one that utilizes some aspects of IPD yet maintains much of the traditional structure or organization as it has existed for many years.

Those that look upon IPD as a significant shift in the way we work will point to the fact that IPD represents a true cultural shift in the way a project is delivered; primarily where project participants seek to achieve the project goals above their own individual goals and utilize tools that aid in the achievement of that goal. While building information modeling (BIM) is not a staunch requirement of IPD, BIM is the tool that facilitates the achievement of many of the IPD goals.

Whatever your stance on the IPD issue, one area that seems to have been overlooked in the literature is what effect IPD can have on the cash flow of the participants. One of the main levers which makes IPD work delays the payment of profit to the parties. As many of the participants work on very thin profit margins, a shift in the pay cycle can have a significant effect on the cash flow of a company. Poor cash flow is most often pointed to as the number one cause of contractor failure.

The purpose of this study is to investigate how IPD, as currently practiced, changes the cash flow of the general contractor and to quantify the cost of this change. By realizing the cost a shift in cash flow might have on a company, the company is in a better position to modify terms of the contract to protect the interest of all involved. A case study approach will be utilized to aid in the quantification of this effort.

2 Review of Integrated Project Delivery (IPD)

The American Institute of Architects (AIA) introduced the most quoted definition of IPD in its publication *Integrated Project Delivery: A Guide* (AIA, 2007a). “Integrated Project Delivery (IPD) is a project delivery approach that integrates people, systems, business structures and practices into a process that collaboratively harnesses the talents and insights of all participants to optimize project results, increase value to the owner, reduce waste, and maximize efficiency through all phases of design, fabrication, and construction.”

The AIA goes on to state that “IPD leverages early contributions of knowledge and expertise through utilization of new technologies, allowing all team members to better realize their highest potentials while expanding the value they provide throughout the project lifecycle.” And “[a]t the core of an integrated project are collaborative, integrated and productive teams composed of key project participants. Building upon early contributions of individual expertise, these teams are guided by principles of trust, transparent processes, effective collaboration, open information sharing, team success tied to project success, shared risk and reward, value-based decision making, and utilization of full technological capabilities and support. The outcome is the opportunity to design, build, and operate as efficiently as possible.” (AIA, 2007a)

This definition and statement of the AIA lays the framework for a process that differs significantly from the traditional design and construction processes. The following characteristics differentiate IPD projects from projects delivered using a traditional approach: (1) a multi-party contract, (2) early involvement of key participants, (3) collaborative decision making and control, (4) shared risks and reward, (5) liability waivers among key participants, and (6) jointly developed project goals (Ghassemi, 2011). All of the above characteristics must be incorporated in a project for IPD to be realized in its purest form (Sive, 2009).

In a traditional project delivery scheme there will be tens, if not hundreds, of traditional, two-party transactional contracts from the owner-architect agreement, owner-general contractor agreement, general contractor-subcontractor agreements, down to the subcontractor-supplier agreements. Each of these contracts align two parties together, each trying to achieve its individual goal, sometimes at the expense of the other party.

IPD contracts are referred to as relational contracts because consideration is given to the process, not just to the end product (Pelberg, 2009). A number of approaches have been suggested and utilized in order to achieve this relational contract scheme. Some advocate forming a “single purpose entity” to plan, design and construct the project. The entity can be a partnership, limited liability company (LLC), or limited partnership (LP), to name a few – with the project participants being partners or members of the entity. This, in effect, makes the participants agents for one another; thereby requiring each to put the others interest ahead of their own. Others recommend having a multi-party agreement (e.g., AIA C191, ConsensusDocs 300) that includes at a minimum the owner, architect and general contractor; but can also include major subcontractors as parties to the agreement.

IPD requires that key participants form a team early in the process to collaborate, set goals and insure that potential problems or inquiries are addressed in a timely fashion.

Mutual respect and trust is the single most important principle of IPD (AIA, 2007b). Often the approach is to have a two tier team approach. One team, the executive team, is comprised of the owner, architect and general contractor (again, at a minimum). This team meets regularly and normally must make unanimous decisions. A second team includes the participation of major subcontractors and consultants. This team acts as an advisory group for the executive team.

To determine if a project is truly IPD or not, one only has to look at how the compensation and risk are handled. In a true IPD project, a profit pool is established whereby the participants' profits or fees are placed in a common pool. The profit pool is distributed after the project goals are analyzed with the distribution based upon the achievement of established goals. This, in essence, is a cost-plus basis where the owner guarantees the direct cost, but the participants' profits and potential bonuses are dependent upon the project outcome (AIA, 2007a). Bonuses may be added to the profit pool by the owner upon the teams' achievement of established goals. The bonus portion is often referred to as an incentive compensation layer (ICL) and is often plus or minus 20% of the profit pool (AIA, 2009). It is in this incentive compensation layer that the participants cash flow can be harmed. Utilizing traditional project delivery the participants earn profit with each monthly billing and that profit serves to enhance their cash flow position. In IPD the profit is withheld until the project goals are met which typically coincide with the completion of construction.

Risk sharing is an integral part of an IPD project and, in theory, there should be no legal battles among the participants. The parties are encouraged to agree to liability waivers and thus have established provisions to prevent legal disputes. As such, insurance and bonding requirements should be held to minimum cost thresholds. However, the insurance and surety industries are based upon risk analysis; and IPD does not have enough history to allow the insurance industry to truly reflect the savings that should be achieved. To illustrate this point, the Ghassemi report includes brief case studies on nine IPD projects (Ghassemi, 2011). Of the nine projects, only five of the projects used multi-party contract arrangements; and only one project reported that the contracts included liability waivers among the participants. Further, only four of the projects reported that surety bonds were not required. This illustrates that, as currently practiced, more projects are IPDish than IPD.

3 Methodology and Results: Case Study

The purpose of this study is to investigate the changes that might occur with a company's cash flow on an IPD project. This was accomplished by utilizing the case study approach. Data was obtained from a general contractor¹ on an actual project in order to investigate how the cash flow might vary from a traditional contract and billing cycle to a project organized and billed in accordance with the IPD philosophy and contracts in place. While it must be kept in mind that compensation distribution and timing is a key point in contract negotiations, the case study will be used to show possible extremes in the process.

¹Robins & Morton, Birmingham, Alabama. Thanks to Robins & Morton for providing the "real world" data utilized in this study.

The case-study project is a recently completed project with a budget of nearly \$130 million. The construction schedule was three years. While projects of all size can utilize the IPD methodology, most agree that it is best suited for larger projects. Ghassemi observed in his study projects ranging in budgetary size of \$10 million to \$1.7 billion (Ghassemi, 2011) with the median project size of \$150 million.

Table 1 illustrates the monthly billings for the case-study project. With a traditional cost-plus contract the fee will be billed and received with each monthly billing. With an IPD contract the fee would be paid by the owner in accordance with the monthly billing, but would be paid into an incentive compensation pool (ICP) which is to be distributed once the project objectives and incentives are analyzed for achievement. Assuming the project metrics are met, the participants (the general contractor in this example) would then receive their fee. While this study focuses on the general contractor, it should be kept in mind that all participants to the contract could potentially be subjected to the same constraints.

The fee received on the project based on traditional monthly (30-day) billings with a 15-day pay cycle has a present value of \$2,596,099 (Table 1). Delaying the fee until the goals of the project are achieved at the completion of construction results in a reduced present value of the contractor's fee in the amount of \$2,300,950 or \$295,149 less than the present value of the fee received on a monthly basis. Assuming a 6% discount rate, this amounts to a loss to the contractor of 10.6% of its fee or 0.23% of the contract amount. While this amount may be lessened with a different contract structure, the true IPD contract typically treats the goals as either a "yes" or a "no" and has little room for "partially achieved" goals (Becerik-Gerber, 2010).

This works to the disservice to the contractor as the IPD contract will generally be looked upon as a "cost plus" type contract where the contractor is getting reimbursed for all costs associated with the project and paid a fee for their work effort. The time and materials that the contractor includes in its billing to the owner generally does not include a cost of "financing" the project. In a lump sum type contract or guaranteed maximum price (GMP) contract, the contractor anticipates the costs of financing the project and should include this cost as a part of his estimate to the owner. This, however, is not a standard practice of cost plus contracts (Autodesk, 2008, NASFA, 2010).

Table 1. Monthly Billing and Fee; \$129 Million, 36 Month Project

Month #	Monthly Billing	Traditional CM Fee Included in Monthly Billing	Present Value of Traditional CM Fee
1	\$1,598,195	\$38,226	\$37,752
2	\$3,814,081	\$91,226	\$89,647
3	\$1,819,314	\$43,515	\$42,549
4	\$4,139,104	\$99,000	\$96,321

21	\$2,719,641	\$58,544	\$52,329
22	\$2,301,816	\$49,820	\$44,310
23	\$3,448,322	\$73,960	\$65,453
24	\$1,697,340	\$36,538	\$32,174
25	\$822,297	\$17,701	\$15,509
26	\$4,946,925	\$23,591	\$20,567
27	\$809,324	\$17,422	\$15,114
28	\$1,344,821	\$28,949	\$24,988
29	\$823,242	\$17,721	\$15,220
30	\$941,624	\$20,270	\$17,323
31	\$253,594	\$5,459	\$4,642
32	\$2,669,245	\$6,499	\$5,499
33	\$269,524	\$5,802	\$4,885
34	\$98,602	\$2,123	\$1,779
35	\$56,457	\$1,215	\$1,013

36	\$168,965	\$3,637	\$3,017
37	\$400,283	\$4,588	\$3,786
	\$129,504,726	\$2,788,050	\$2,596,099

4 Conclusion

Collaboration among the parties in the building process has received increased attention and emphasis with the gain in popularity of building information modelling. While BIM, in itself, does not require a change in the ways the parties align themselves contractually, it provides an opportunity for forward looking individuals to explore new and innovative ways of accomplishing the goals of a project. One such result is IPD.

True integrated project delivery should result in all participants involved in the building process to act as team members in the truest sense, where the members not only look out for their interests but the interests of the team as a whole. While this concept has been around for a number of years, it truly is in its infancy from a practical standpoint. For IPD to reach its full potential successfully, the team concept must include all major participants.

One of the overlooked aspects of IPD has been the change in the compensation schedule of the participants. While this case study has focused on the general contractor, it applies equally to the other participants who would be involved with the compensation pool. By delaying one's compensation until definable project goals are achieved, without the benefit of including this in your contract price, has a net result of discounting your overall profit or fee. In this case study, this amounted to 0.23% of the total project budget or stated in other terms about 10% of the contractor's fee would have been dissipated by the lag in payment.

Participants should keep this in mind when they are entering into an IPD agreement. In an IPD agreement provisions can be negotiated that would alleviate the financial burden that is placed on the participants by altering those terms and conditions which affect their cash flow.

The Impact of Contract Administration on the Development of Small to Medium Contractors in Gauteng Province

Siphiwe Joshua Nkosi¹ and Hendrik F. Prinsloo¹

¹Department of Construction Economics
University of Pretoria, Pretoria, 0001
South Africa

Email: joshnko@mweb.co.za; hendrik.prinsloo@up.ac.za

Abstract:

Small to medium size contractors that have entered the construction industry since 1994 democratic elections have not grown rapidly to participate in contracting opportunities created by the government infrastructure programme. These contractors are responding to procurement reforms that were initiated by government. These procurement reforms have over a period of two and half decades increased the number of contracting opportunities for small to medium contractors but they have not been very successful in building their capacity to procure and complete larger contracts. This study suggests that the bulk of government construction expenditure in the medium term will be directed to larger contracts. The current mismatch in contracting capacity will be accentuated as too many small to medium contractors are pursuing fewer opportunities. The unhealthy competition amongst these contractors ensures that too few of them are able to procure successive contracts hence build up capacity to grow into larger construction enterprises.

The focus of the study was on how contract administration capability could assist the small to medium contractors with potential to complete successfully larger and/or multiple construction projects. The findings suggest the small and medium contractors have only accumulated basic knowledge of contract administration which may be sufficient for smaller contracts but is inadequate for more complex contracts. To grow the small to medium sized contractors a more in depth comprehension of technical and contractual issues relating to construction work are required. The research methodology followed was to review the relevant literature, conduct structured interviews with contractors, policy makers and project managers.

Keywords:

contractor administration, contract development, construction expenditure, small to medium scale contractors

1 Introduction

Construction industry in South Africa has grown consistently over the last decade. The industry is on the brink of sustained boom for at least the next decade if planned infrastructure programmes that underpin the country's economic development strategy are realised. Treasury is committed to infrastructure spending around R787 billion between 2009 and 2011 and this amount has since been increase to about R840 billion between 2010 and 2012 (South African Treasury, 2009 and Industry Insight, 2010)

This suggests a sustained contracting opportunities over the next few years that are predicated on public infrastructure spending. These contracting opportunities are inherently larger, technically complex and more administratively involved. The appropriately capacitated medium size contractors can augment the already stretched construction capacity to levels required to meet projected economic growth and planned construction projects.

There are too many low Construction Industry Development Board (CIDB) graded contractors that are not equipped to partake in the bulk of projects within the government infrastructure programme (Cameron, 2007). The question is how to assist these contractors to build capacity so that they can consistently and successfully complete larger project. In other words what are necessary capabilities for these contractors to grow into medium sized entities that can execute larger and/or multiple projects? The inability of low CIDB graded contractors to improve their capabilities has persisted despite more than a decade of governmental contractor development programmes.

The aim of this study was to ascertain whether the advanced knowledge of contract administration on the part of small to medium scale contractors is a requirement to grow capacity of these enterprises.

It was also investigated how low grade contractors can optimally mobilize and build-up contract administration expertise and systems necessary for larger projects in the context where resources are scarce, expensive and concentrated in already larger contracting entities.

2 Literature Review

Struggling small to medium sized contractors is an international phenomenon particularly in developing countries. A few international writers have attempted to explain the reasons for failure of small to medium scale contractors to grow into larger contractors.

Three pertinent international research works by Schleifer 1989, International Labour Office (1987) and Ganesan (1982) were reviewed and collated in order to provide theoretical grounding of the causes of construction enterprises failure. The reasons for failure of the construction enterprises to grow documented in each research work are briefly summarized below.

The seminal research on constraints to growth of small to medium contractors, based on experience of developing countries in Africa and Asia continents, was conducted by the

International Labour Office (1987). This document argues that the factors which individually or in concert can stymie the performance, consequently the growth or even the survival of small to medium contractors fall under the following categories:

Market and business environment in which the contractor operate;

Conduct of the clients; and

Inherent inadequacies of the contractors themselves.

The first two groups factors viz market and business environment are beyond the control of the small to medium contractors. The document identified the key market or environmental factors as access to work, access to finance, delayed progress payments, complex tender document, access to material and plant and scarcity of skilled labour.

International Labour Office (1987) lists the following five problems that are inherent to contractors:

2.1 Technical understanding

Most small- scale contractors have difficulties in understanding the simplest technical drawings.

2.2 Estimating and tendering

“Small scale contractors are not usually able to afford the fees of professional advisors, nor does their workload justify employing a full-time estimator instead, the contractor himself tends to compile or commit to memory cost data based on his own experience...” (ibid: 46). Inevitably the contractor can seriously underestimate the new types of projects or large projects (ibid: 46).

2.3 Contract Law

It is very rare that the works on site proceed exactly as set out in the tender document as consultants make errors, unforeseen circumstances do arise and clients also change their requirements (ibid: 32). Established contractors with good understanding of construction contract law in terms their obligation and rights will make the most of the changes.

2.4 Planning and Management

Deficiencies in planning and management skills represent probably the greatest single stumbling block among small scale contractors. “Unlike the small building project on which a single building team may work sequentially on each element, larger projects may have groups of specialist workers, each of which can be dependent on the others. ... Planning, logistical and site management thus become more sophisticated and more critical “(ibid: 32).

2.5 General Bookkeeping

In order to obtain working capital loan, guarantee and insurance from financial institutions the contractor should be in a position to furnish projected income and expenditure in contract work and company’s financial statements. Without assistance

from financial institutions the contractor will not be able to proceed with the project even if he has won a tender.

All the above factors listed except estimating and tendering is at play only once the contractor has been appointed and therefore is part of contract administration.

Another investigation done in the United States of America by Schleifer (1990) identified ten reasons why the small to medium contractor do not realize profit on project/s thus fail to grow, stagnate and/or decline. There are two categories of these reasons "...five relate to the company's business strategies or practical consideration and five relate to fiscal or accounting consideration" (Scheilfer, 1990: 16). They are:

2.6 Increase in Project Size

Unfamiliarity with new Geographic Area

2.7 New Type of Construction

Changes in Key Personnel.

2.8 Lack of Managerial Maturity in Expanding Organizations

2.9 Poor use of Accounting Systems

2.10 Failure to Evaluate Project Profitability

2.11 Lack of Equipment Cost Control

Poor Billing Procedures

2.12 Transition to or Problems with Computerized Accounting

In the early 1980, S. Ganesan, a researcher with the Asian Productivity Organization investigated the performance of small contractors in five countries namely Sri Lanka, Singapore, Thailand, the Philippines and Japan identified a number of generic problems leading to their failure. These are: labour shortage, access to finance, lack of policy and procurement of work

3 Research Methodology

The first step in investigating the research questions required sourcing of relevant literature amongst academic books, journals, seminar papers, proceedings of workshops, brochures of agencies dealing with constraints small to medium-scale contractors and solutions thereto. The aim of the literature review was to explore principles and theoretical foundation that can inform analysis of constraints faced by small to medium contractors and some suggested solutions thereto.

To explore the perceptions of the construction industry participants on the role of contract administration in development of construction contractors, structured interviews were conducted with key informants particularly leaders of the small to medium enterprises, CIDB officials and organized association of contractors. There were also interviews with client representatives' managing projects, senior officials

responsible for programmes providing managerial training to contractors, policy makers and relevant service providers to contractors.

A stratified random sampling technique was employed to identify respondents that were appearing in the CIDB list. For cost and time reasons only contractors that are domicile in Gauteng Province was included in the sample. The contact details of contractors based in Tshwane and Johannesburg as they appear in CIDB data base was used to compile a sample. In case where the contractor was for whatever reasons not able or unwilling to participate in the interview s/he will replace by another contractor of similar characteristics.

A sample of fifteen contractors was considered sufficient to adequately reflection of the total population. Such a sample size also ensures that the study is completed within the time and financial constraints.

It is however acknowledged that though there may be regional difference but the results should sufficiently robust to point to the national trends.

4 Findings and Discussion

4.1 Generic Characteristics of the Contracting Enterprises

All the contracting enterprises that were interviewed had their day-to-day operations managed by the equity owners who have spent the better part of their working life in the construction industry. Only 28% of the interviewees did not have long careers in the industry. Most owner managers had spent between 6 to 30 years in the construction industry. The average duration that they had run their businesses was 10 years. The shortest duration at the helm of the enterprise was 4 years.

These enterprises rarely changed equity ownership despite the fact they have been around for a decade or more. Amongst the interviewed enterprises 85% were still in the hands of the original owners.

4.2 Number of Concurrent Projects in 2008 and 2009

Table 3. Concurrent Projects

Number of Projects	2008	2009
0	0%	15%
1-2	55%	70%
3-4	30%	15%
5-6	15%	0%

Table 3 shows that on average handled two contracts per year. Only 45% in 2008 and 15% in 2009 of interviewed contractors had more than two contracts in their order books. This could perhaps be ascribed to both their fledgling capacity and unavailability of work.

4.3 Contract Administration Capacity

The owner managers were personally responsible for all contract administration matters on all the projects undertaken by the enterprises in 70% of cases reviewed. Most owner managers had some additional support from the site agent, health and safety office, quantity surveyor or project manager depending on nature of the project. The owner managers tend to be involved in matters that directly and immediately impacted on project finances (e.g.: scope of work, time and financial claims, quotes and invoices) and matters relating to on-site management (e.g. work quality, day-to-work plan, receiving site instructions, labour recruitment, security arrangement etc).

4.3.1 Owner Manager Contract Administration Experience and Formal Training

The owner managers of medium size construction enterprises have some experience in contract administration with seven years being the average duration. This refers to leadership and oversight responsibilities on projects.

4.3.2 Site Agent/Project Manager Contract Administration Experience and Formal Training

Table 4. Site/Project Manager's Experience

Site Agent/ Project Manager Years of Experience	%
Less than 5 Years	43
Between 5 – 10	14
More than 10 Years	43

The distribution of years of construction experience accumulated by site agent/project manager is bi-modal as about 43% have in excess of 10 years experience and the other 43% has less than 5 years experience. The group with 5-10 years experience constituting only 14%.

Table 5. Site/Project Manager's Training

Site Agent/ Project Manager Formal Training	%
Trade Certificate	0
Matric	0
Post-Matric Requisite Diploma/Certificate	86
Post-Matric Requisite Degree	14

All the site agents/project managers had Post-Matric construction qualifications which are equivalent of National Qualification Framework (NQF) Level 5 as per South African Qualification Authority prescribed standards. The NQF Level 4 National Certificate in Construction Management "...is regarded as the minimum competence necessary to successfully manage a contracting enterprise and for supervising building and construction works" (CIDB, March 2009: 10).

The survey suggests that the respondents had at least one person either the owner manager or the site agent/project manager, with reasonable experience and formal training on certain built environment discipline.

The person performing contract administration functions were generally working for the enterprises on full-time basis. These were either shareholders or permanent employees. There were some instances where short-term contract employees or consultants such as estimators or quantity surveyors were used on projects. This tend to happen on larger building projects usually in excess of R5 million.

4.3.3 Application of Contract Administration Knowledge Areas

In order to understand how the various contract administration tasks were executed by each contractor, the respondents were asked to identify persons to whom such tasks were assigned on current or recent projects. In such case a point was allocated to the relevant position. These points were tallied to determine the preponderance of specific task being assigned to a particular position. The results that were converted into percentiles are shown below:

Table 6 Administration/Financial Tasks

Administration/ Financial Tasks	Contracts Director/ Manager	Project Manager	Site Agent/ Foreman/Clerk	Quantity Surveyor	Health & Safety Officer	Estimator	Other ¹
Preparing Quotes for V.O's	52%	4%	4%	32%	0%	8%	0%
Preparing Payment Certificate	47%	0%	9%	38%	0%	6%	0%
Compilation and safekeeping of project records and accounts	28%	13%	59%	0%	0%	0%	0%
Processing various project authorization	38%	0%	46%	0%	0%	0%	6%
Ensuring compliance with health & Safety	8%	0%	0%	0%	92%	0%	0%

¹Other: main contractor/ consultant/ senior JV partner

The review of the Table 6 suggests that the contracts director / managers, who are invariably the owner managers, predominantly took responsibility for matters with the immediate financial implications e.g. preparation of quotes for variation orders and preparing payment certificate. If for some reason the owner manager is unable to fulfil this role, particularly in building projects, an external quantity surveyor was contracted usually on short term basis essentially as a cost consultant. The site agent was primarily

responsible for on-site administrative matters like compilation and safekeeping of records, obtaining various authorizations. All the matters relating to compliance with health and safety issues were almost entirely left external health and safety officer.

4.3.4 Contract/Regulatory Compliance

Table 7 Contract/Regulatory Compliance Tasks

	Contracts Director/Manager	Project Manager	Site Agent	Quantity Agent	Other ²
Preparing extension of Time/Financial claim	80%	0%	0%	12%	8%
Identify Site Instruments requiring variation order	26%	26%	18%	30%	0%
Ensuring compliance with Empowerment Regulation	54%	8%	30%	0%	8%

²Other: Senior JV Partner

Similarly in this group of the tasks those involving the immediate financial consequences viz time and financial claims were the prerogative of the contracts director /manager. However the identification of site instructions triggering variation orders was almost split evenly across project management staff i.e. contract director/manager, site agent or quantity surveyor. This may be an indication of the difficulties on the part of owner manager (contracts director /manager) who appropriates all tasks with immediate financial consequences to himself/herself when he/she not is always on site to receive and effect all the site instructions. It is however worth noting that although preparations of time and/or financial claim and identifying site instruction that should trigger variation order were assigned to certain personnel. Empowerment compliance which normally includes local employment, appointment of local/marginalized enterprises and training thereof seem to involve both the owner manager and site agent although more often than not the former will take the lead.

4.3.5 Construction Technology

Table 8. Construction Technology Tasks

	Contracts Manager/ Director	Project Manager	Site Agent	Quantity Surveyor	Other ³
Ensuring that works comply with drawings and specification	23%	19%	58%	0%	0%
Oversee preparation of shop drawing and contractor alternative drawings	8%	0%	16%	0%	76%

³Other: Not performed yet

Building technology is the responsibility of the site agent, although there are instances where because of size of the project that is too small to employ an additional person, the owner manager perform these tasks him/herself. As a rule these contractors do not offer alternative tenders nor prepare shop drawings during construction period. This may suggest that generally these contractors are more comfortable with their routine or run of mill technical knowledge.

4.3.6 Site Management

Table 9. Site Management Tasks

	Contracts Manager/ Director	Project Manager	Site Agent	Quantity Surveyor	Other ¹
Setting out and day-to-day planning of works	8%	0%	92%	0%	0%
Projects Scheduling	57.5%	31%	11.5%	0%	0%
Appointment of subcontractors and negotiating with support	65%	15%	20%	0%	0%
Arranging site security	23%	15%	46%	0%	15%
Quantity Control	8%	11.5%	64.5%	8%	8%
Progress monitoring, recording and reporting	71%	14.5%	14.5%	0%	0%
Reading drawing and specification	42%	11.5%	46.5%	0%	0%
Expediting Issuance of Completion Certificate	50%	11.5%	8%	22.5%	8%

¹Other: Senior JV Partner/consultant/Main Contractor

The allocation of site management tasks still were still divided according to on-site and head office functions. Consequently the site agent was primarily responsible for setting out day to day planning of work, quality control of work production, ensuring the work is according to drawing and specification and overseeing site security arrangement. On the other hand the owner manager took responsibility for work programme from start to finish, appointment of sub-contractors and suppliers, regular progress reports and recording and securing the release of retention and guarantee after issuing of completion certificate.

5 Conclusion and Further Research

5.1 Conclusions

The recent developments in construction industry have combined to create unprecedented business opportunities for small to medium sized contractors. The procurement reforms led by public sector employers have seen emerging contractors that are ordinarily smaller in scale dramatically increasing their share of construction work in the last fifteen years. This was achieved by legislative and policy changes that allowed enterprises owned by previously disadvantaged persons to get preferential treatment. This has led to preponderance of smaller sized contractors in the industry which is exceeding the scale of contracting opportunities. This proliferation of lower CIBD graded contractors has been fuelled by increasing public sector spending in construction industry since the late 1990s.

The survey in Gauteng shows that the overwhelming majority of small to medium sized contractors that recently entered the industry are owned by pioneers who are managing all operations of the enterprise at the beginning. When the enterprise grows the owner-

manager usually employs a person to oversee the work production on-site. The growth of the enterprise occurs naturally, as it increases the number and size of projects on its order book. There has been no instance of pooling of resources amongst different enterprises through mergers or acquisitions. Consequently the growth to medium size entities has been painstaking and protracted. The owners of these enterprises were normally one person, family members, friends or colleagues who have known and/or work together for years. (CIDB, 2004:39). Whilst this ownership arrangement has ensured stability of these enterprises, operating as 'one person' or family business restricted capacity growth. The enterprises relied on a person's, friend's or family's resources or enterprise's savings to growth.

The research suggests that the majority of recently established contractors have found it difficult to grow to such an extent to enable them to successfully secure and complete large or multiple contracts. This treatise suggests that this could in part be ascribed to inadequate contract administration knowledge. For historical reasons these enterprises neither have access to the pool of persons with advanced expertise nor are they organizationally flexible enough to quickly consolidate such advanced expertise currently located amongst different enterprises.

5.2 Recommendations

Solutions to overcome these endemic inadequacies of small to medium contractors have to be found. It should however be accepted that not all small to medium contractors can improve their CIDB grading. The ratio of the number of larger contracting opportunities relative to the number of contracting enterprises is also comparatively high. It is therefore imperative that small to medium sized enterprise improve their contract administration capability that will in-turn allow them to successfully tender and execute larger projects. To this end the following is recommended:

The existing and already successful contractor development programme should be overhauled to improve structured training and mentoring of the small to medium contractor. The training and mentoring should be directed particularly at advanced aspects of contract administration particularly construction contract law, time and financial management and relevant procedures, identifying project scheduling of complex projects and value engineering. This knowledge could be imparted to the contractors through short courses tutoring, project mentoring/coaching or combination of both.

The small-scale construction enterprises that have generally evolved as one-person or family enterprise have limited ability to grow and consolidate beyond a certain threshold without access to professional capability (CIDB, 2004: 39). Mergers and acquisition should be deliberately encouraged to reduce the numbers of low grade contractors and increase the number of high grade contractors. The objective is to create a critical mass of resources to undertake larger and multiple contracts. It is however important to ensure that only those who combine their resources have a potential to grow. It should also be noted that mergers and acquisitions may also have disadvantages associated with it. It is possible that some staff members can become redundant due to a duplication of certain key functions. Different business objectives may also lead to conflict.

Cost and value management

Key Construction Performance Indicators for Employers and their Agents

Hendrik J Marx

Department of Quantity Surveying and Construction Management,
University of the Free State, South Africa

Email: marxhj@ufs.ac.za

Abstract:

Annual monitoring of the condition of the South African construction industry is vital to enable government and other role players to evaluate the impact of current interventions and to timely and pro-actively implement revised legislation, strategies and development programs to act as an updated roadmap for the future well-being and growth of the industry. This monitoring of the construction industry is done annually by the Construction Industry Development Board (cidb) by using key performance indicators.

A database with contact particulars of employers, contractors and agents (consultants) involved in more than 2800 projects completed in 2009 was compiled. Three separate survey forms were faxed or e-mailed to them. Their responses were captured in a Microsoft Access database.

The scope of this paper is limited to the results received from the employers and agents. Where possible the results were compared with those obtained from previous similar surveys.

It was found that only 46% of agents were paid on time. Contractor quality was discarded as being of any importance in many tenders awarded. There was a strong indication of political intervention in the allocation of tenders.

This paper contributes to the understanding of the construction industry and gives a marked-up roadmap with pitfalls to avoid on the way forward. Government can make use of the results obtained to timely and pro-actively implement revised legislation, strategies and development programs to ensure the well-being and growth of the industry.

Keywords:

CII, Construction Industry Indicators, Key Performance Indicators, KPI

1 Introduction and Literature Review

The Construction Industry Development Board (cidb) Act (Republic of South Africa, 2000) was passed in 2000 to establish a statutory body aimed at driving an integrated construction industry development strategy. This body was necessary as the

construction industry plays an indispensable role in the South African economy by providing the physical infrastructure which is fundamental to the country's development. The construction industry operates in a uniquely project-specific and complex environment, combining different investors, clients, contractual arrangements and consulting professions. It impacts directly on communities and the South African public at large, and its improved efficiency and effectiveness will enhance quality, productivity, health, safety, environmental outcomes and value for money. In terms of this act, the cidb 'may develop target and performance indicators related to best practice standards and guidelines and establish mechanisms to monitor their implementation and evaluate their impact'.

Construction Industry Indicators (CIIs) have been developed by the Department of Public Works and the cidb with the assistance of the CSIR (van Huyssteen, van Heerden, Perkins and Gyimah, n.d.: Online) to play a useful role in developing a sustainable industry and to be adopted as a tool for improving performance in the South African construction industry. The CIIs of the cidb rely heavily on international experience and particularly those indicators adopted in the United Kingdom. In the United Kingdom the first Key Performance Indicators (KPIs) were published in 1999 in response to the Rethinking Construction report by Egan (1998). These KPIs had three objectives, namely:

- To provide companies and projects with a simple method of establishing a performance measurement system;
- To provide organisations with a straightforward method of benchmarking their performance against others in the construction industry; and
- To track long term trends in performance, and specifically, to demonstrate whether the construction industry was achieving the targets set out in Rethinking Construction.

(Rethinking Standards in Construction, 2006: 3)

Cost, time and quality are the three basic and most important performance indicators in construction projects followed by others such as safety, functionality and satisfaction (Chan and Ada, 2004: 203-221). Based on the Egan report the Movement for Innovation and Construction Best Practice Programme (CBPP) was formed and is now recognised as a leading organisation involved in the production of KPIs within the industry (Beatham, Anumba and Thorpe, 2004: 93-117). The KPIs launched by the CBPP are: client satisfaction, product and service, profitability, productivity, defects, safety, construction time and construction cost. These KPIs were benchmarked within the construction industry and have been very successful in introducing many companies to the subject of performance measurement (Beatham et al., 2004: 93-117).

The cidb CIIs measure the performance of the South African construction industry by measuring employer satisfaction with the project milestone dates achieved, construction costs versus tender amount, contractors' performance, agents' (consultants') performance, and the quality of materials used. The contractors' satisfaction is measured by their profitability, the performance of the employer and his agents, the quality of the contract documentation, the management of variation orders and claims,

payment delays and the performance of their materials suppliers. The procurement indicators measured are obtained from the agents involved and include contractor performance issues utilised in the adjudication of tenders, the type of procurement procedure used, and the contracting strategy adopted.

The cidb CIIs described above have been captured since 2003, and are currently being captured in partnership with the Department of Quantity Surveying and Construction Management of the University of the Free State. This report is part of a series of annual papers (Marx 2009) presenting the results of this continuous survey project. It is a report on the results of the 2010 survey for projects completed in 2009.

2 Methodology

A database, with contact particulars of employers, contractors and agents involved in 2807 projects completed in 2009, was compiled. Three separate survey forms were faxed or e-mailed to the contractors, employers and agents of these projects. Their responses were captured in a Microsoft Access database. The average perspectives of the respondents were determined for different project types, employer categories and provinces. All questionnaires made use of the scale shown in Table 1 to measure satisfaction levels.

Table 1. Definition of the % satisfaction levels

Dissatisfied			Neither Satisfied nor Dissatisfied				Satisfied		
10	20	30	40	50	60	70	80	90	100

3 Scope

The CIIs of the cidb need to evolve from the lessons learned from previous surveys, and are therefore subject to change and refinement. Furthermore, the CIIs used were only mainline indicators. Questions were not asked to pin-point the exact reasons for all problems experienced. The CIIs considered were only the project related indicators.

From the 2807 completed projects in the database, the contact particulars of 2807 contractors, 2624 employers and 1520 agents were available. Survey forms were received back from 1053 contractors, 434 employers and 445 agents reflecting response rates of 37,5%, 16,5% and 29,3% respectively. The scope of this paper is limited to the results received from the employers and agents.

4 Discussion of the Agents' Survey Results

4.1 Agent survey response distribution per project type and employer category

Table 2 gives a summary of the survey forms completed by agents. The number of survey forms completed is indicated for different employer categories and project types, with the purpose to evaluate whether responses were obtained for all types of construction projects and all the different employer bodies.

Table 2. Agent survey response distribution per project type and employer category 2009

Project Type	Total No. of projects	23	13	7	16	33	6	2	0	% of Total Survey Results
Residential Building	38	15	-	2	14	7	-	-	-	9
Non-residential Building	100	34	12	13	23	9	3	6	-	23
Civil Works	210	33	26	14	19	97	18	3	-	47
Mechanical Works	40	8	5	1	7	14	4	-	1	9
Electrical Works	42	7	9	2	8	16	-	-	-	9
Special Works	15	6	5	-	-	2	2	-	-	3
Not Specified	-	-	-	-	-	-	-	-	-	0
Total No. of Projects	445	103	57	32	71	145	27	9	1	
		Private sector	Public Corporation e.g. ESKOM, ACSA	National Department	Provincial Department	Metropolitan Council	Regional / District Council	Public Private Partnership	Not Specified	
		Employer Category								

Table 2 shows that the largest group of responses received were from civil works (47%) and non-residential building projects (23%) and projects of the private sector (23%), provincial departments (16%) and metropolitan councils (33%) were best represented in the survey.

The percentage survey results received from each province was also correlated with the construction activities in the province, as represented by cement sales in the particular province, to establish whether the survey captured a well distributed response from all provinces. This is shown in Fig. 1 and was found to be the case. The results are presented per project type and per client category to ensure that the results for less represented project types do not disappear in the average of all projects.

4.2 Contractor performance issues utilised in the adjudication of tenders

Agents were requested to indicate which contractor performance issues were taken into account during the tender adjudication process and the results are indicated in Table 3 for different employer categories.

Figure 1: Correlation between survey responses received and cement sales per province
(Source: Cement and Concrete Institute)

Table 3. Contractor performance issues used in the adjudication of tenders 2009

Performance Issues	% of Projects in each Employer Category using different Performance Issues						
Financial offer	31	16	17	10	5	11	11
Financial offer and preference	14	23	53	38	54	50	22
Financial offer and quality	21	11	3	12	6	4	34
Financial offer, quality and preference	34	50	27	40	35	35	33
	Private Sector	Public Corporation e.g. ESKOM, ACSA	National Department	Provincial Department	Metropolitan Council	Regional / District Council	Public Private Partnership
	Employer Category						

Table 3 shows that even the private sector incorporated preference in 48% of all their projects. No longer are price and quality the only issues evaluated and tender allocation based on financial offer, quality and preference was most popular (34%). Table 3 shows that there were still a large number of projects where financial offer and preference were the only criteria used to allocate tenders. It is alarming that financial offer and preference were the only criteria considered in 53%, 38%, 54% and 50% of projects for national and provincial departments, metropolitan councils and regional/district councils respectively. In other words, the quality i.e. capability, training, performance and track record, of the contractors, were considered as being of no importance to select a contractor to do work for the employer. This political strategy to support and build emerging contractors should be re-evaluated by government.

4.3 Agents' satisfaction with the time allowed for planning

Table 4 shows the agents' satisfaction level with the time allowed by the employer for project planning. Agents were least satisfied (68%) with the national departments for

the time they allowed for planning. According to the results received the time allowed for thorough planning and documentation is, generally speaking, not problematic.

Table 4. Agents' satisfaction level with time allowed for planning 2009

% Satisfaction per Employer Category						
78	76	68	75	78	87	82
Private Sector	Public Corporation	National Department	Provincial Department	Metropolitan Council	Regional / District Council	Public Private Partnership
Employer Category						

4.4 Deviation from the tender adjudication procedures

Agents were posed the question whether the employer awarded the tender to the responsive tenderer who achieved the best tender score during the tender evaluation process. The tenders were evaluated by the agents according to the employer's own approved tender evaluation procedures. Non-responsive tenders received were ignored. Table 5 shows the percentage of contracts that were not awarded to the responsive tenderer with the best tender evaluation score per employer category and province.

Table 5. Contracts not awarded to the tenderer with best tender score per province 2009

Employer Category	% Contracts not awarded to the responsive tenderer with best tenderer score								
Private Sector	8 (13)	33 (3)	26 (29)	32 (22)	25 (8)	33 (9)	25 (12)	40 (5)	18 (11)
Public Corporation	11 (9)	0 (2)	14 (14)	8 (13)	0 (2)	17 (6)	0 (1)	0 (2)	14 (7)
National Department	0 (4)	0 (2)	0 (5)	0 (4)	17 (6)	0 (3)	-	-	0 (7)
Provincial Department	13 (16)	-	0 (1)	8 (13)	54 (13)	56 (9)	25 (4)	25 (4)	13 (8)
Metropolitan Council	14 (14)	8 (12)	4 (25)	26 (23)	25 (8)	0 (6)	5 (20)	0 (3)	3 (31)
Regional / District Council	20 (5)	100 (1)	-	11 (9)	-	33 (3)	0 (2)	0 (3)	0 (4)
Public Private Partnership	0 (3)	-	33 (3)	0 (2)	-	-	-	0 (1)	-
The value in brackets is the number of projects involved	Eastern Cape	Free State	Gauteng	KwaZulu-Natal	Limpopo	Mpumalanga	North West	Northern Cape	Western Cape
	Province								

The provincial department of Limpopo and Mpumalanga overruled tender recommendations in 54% and 56% of their tenders awarded. The results are disturbing bearing in mind that it is not based on perceptions of the aggrieved tenderers, but on the knowledge of the independent agents of the employers. This suggests that there may be some form of political intervention, manipulation of results or corrupt / fraudulent practices. The national departments, except in the Limpopo province, performed very

well. Table 5 shows in which provinces and for which employer categories tender adjudication practices should be investigated.

4.5 Payment delays

The average number of days delays between submission of professional fee accounts and receipt of payment is shown in Table 6. The agents' fees were paid within 30 days for only 46% of all projects completed. The provincial departments were the slowest payers with professional fees for 25% of their projects only paid after more than 60 days. Public private partnership employers followed with 22% and metropolitan councils and regional / district councils each followed with 19% of their projects where payments were only made after 60 days or more.

Agents refrain from standing up to their contractual right to be paid on time for fear of losing new project appointments in the future.

Table 6. Payment delay of agents' fees per employer category 2009

Avg. Days Delay	% of Projects with Payment Delay per Employer Category							% of all Projects
≤ 14	22	7	3	6	5	11	11	10
14 to 30	36	47	50	31	31	37	22	36
30+ to 60	32	30	31	38	45	33	45	37
60+ to 90	5	11	10	13	10	8	11	9

Employer Category						

5 Discussion of the Employers' Survey Results

5.1 Employer survey response distribution per project type and employer category

Table 8 provides a summary of the survey forms completed by employers for projects completed in 2009. The number of survey forms completed is indicated for different employer categories and project types.

The table shows that the majority of responses were for civil works (41%) and non-residential building projects (21%). Projects of the private sector (29%), public corporations (20%) and metropolitan councils (25%) were best represented in the survey. The results are presented per project type and per employer category to ensure that the results for less represented project types do not disappear in the average of all projects. The percentage survey results received from each province was also correlated with the construction activities in the province, as represented by cement sales in the particular province, to establish whether the survey captured a well distributed response from all provinces. The result is shown in Fig. 1 and it was found that the survey results were well distributed between provinces.

5.2 Construction commencement milestone dates

Table 9 shows the percentage of projects with the project commencement and completion dates achieved for different project types and employer categories. It is not known whether the reason for a late start was contractors who could not produce their guarantees on time, or employers who did not have the sites ready to hand over to the contractors. Table 9 shows that 96% of all projects started on time and 87% of all projects finished on time. The finish on time date included any normal extension of time allowed for by the contract. Only 79% of the mechanical projects finished on time. This is the project type with the lowest performance. Regional / district council projects had the lowest percentage (76%) that finished on time. It is not known if the reason for late completion is lack of contractor capacity, managerial skills, finances, know-how or perhaps unrealistic construction periods specified by agents or employers.

Table 8. Employer survey response distribution per project type and employer category 2009

Project Type	Total No. of Projects	29	20	5	14	25	5	2	0	% of Total Survey Results
Residential Building	28	17	4	3	2	2	-	-	-	7
Non-residential Building	93	41	19	5	15	8	4	-	1	21
Civil Works	178	30	23	9	29	69	12	6	-	41
Mechanical Works	42	15	7	2	6	8	2	2	-	10

		Private sector	Public Corporation e.g. ESKOM, ACSA	National Department	Provincial Department	Metropolitan Council	Regional / District Council	Public Private Partnership	Not Specified	
		Employer Category								

Table 9. Project start and completion milestone dates 2009

Project Type	Start on Time %	Finish on Time %
Residential Building	96	85
Non-residential Building	95	84
Civil Works	98	90
Mechanical Works	95	79
Electrical Works	94	89
Special Works	100	87
Overall	96	87
Employer Category	Start on Time %	Finish on Time %
Private Sector	95	87
Public Corporation	95	83
National Department	100	91
Provincial Department	97	80
Metropolitan Council	98	93
Regional / District Council	90	76
Public Private Partnership	100	88

5.3 Customer satisfaction

Table 10 shows the average level of employer satisfaction for different project types. These are the performance levels of their agents and contractors and the quality of materials used. Bearing in mind that a score of 80% means satisfied, Table 10 shows that employers were satisfied with the overall performance of their agents, and their contractors and the overall quality of materials used on site. Residential and non-residential building projects received the lowest score (79%) for work defect free at practical completion. Mechanical work projects received the lowest satisfaction level (79%) for the contractor's ability to finish on time. Generally speaking the average satisfaction levels expressed by the employers were high.

Table 11 shows the employers' satisfaction level with the overall performance of the contractors per province. There is an indication of low performance for certain project types in various provinces although the results are in some cases obtained from only a few survey responses.

Table 10 Employer satisfaction 2009

Project Type	Employers' Level of Satisfaction % with						
Residential Building	81	84	83	84	83	79	86
Non-residential Building	82	82	81	83	82	79	85
Civil Works	82	83	83	84	83	82	86
Mechanical Works	83	82	79	84	81	82	85
Electrical Works	83	84	84	87	86	84	87
Special Works	87	84	83	85	84	84	87
	Overall performance of Agents	Overall performance of Contractor	Ability of Main Contractor to finish on time	Quality of Completed Work	Main Contractor's Resolution of Defective Work	Work Defect free at Practical Completion	Overall quality of Materials used

5.4 Employers' own capacity

Table 12 shows the percentage of contracts per employer category where agents were not appointed. The national department delegated all their project design work to agents except for 4% of their projects. This indicates that there is nearly no departmental capacity in among others the engineering, architectural and quantity surveyor fields of work. Furthermore, it is quite likely that the remaining 4% projects were projects such as large painting contracts where technical and professional expertise is not required. It is of great concern that role players in the construction industry has to communicate with officials in government departments who have no or very little understanding of the contractual procedures and technical complexities inherent to construction projects.

Table 11 Employers' level of satisfaction with the overall performance of contractors per province 2009

Project type	Satisfaction Level%								
Residential Building	60 (1)	80 (1)	84 (5)	83 (7)	95 (2)	-	95 (2)	90 (1)	83 (9)
Non-residential Building	80 (10)	67 (3)	85 (35)	81 (16)	83 (3)	93 (3)	90 (4)	60 (2)	79 (17)
Civil Works	84 (28)	83 (11)	81 (23)	86 (40)	82 (20)	84 (14)	78 (11)	80 (5)	83 (26)

3	8	4	11	13	0	13
Private Sector	Public Corporation e.g. ESKOM, ACSA	National Department	Provincial Department	Metropolitan Council	Regional / District Council	Public Private Partnership

6 Conclusions

The main findings of the 2010 survey for projects completed in 2009 were as follows:

- 1) It is of great concern that contractor quality was discarded as being of any importance in 53%, 38%, 54% and 50% of tenders allocated for national and provincial departments, metropolitan councils and regional/district councils respectively.
- 2) Agents were least satisfied (68%) with the amount of time allowed for planning by national departments.
- 3) Only 46% of agents were paid on time within 30 days.
- 4) There is a strong indication of political intervention in the tender adjudication procedures of many employer bodies.
- 5) Only 79% of mechanical works projects were finished on time.
- 6) Employer bodies have very little in-house capacity.

- 7) Employers were satisfied with the overall performances of their agents and contractors and the quantity of materials used.

Abstract:

Lean construction has been predominantly employed by companies to increase their responsiveness to customer needs, through a variety of conduits, including capital and operating reduction mechanisms aligned to quality improvement measures. In this respect, clients and the construction industry need to be aware of the potential benefits of lean construction to projects to encourage them to employ lean construction techniques on their projects. This paper examines the challenges of maximising ‘value’ in lean construction implementation. Lean construction concepts and principles have proven to be particularly effective; and the suitability of lean construction techniques to promote value in construction is raised for discussion. The paper reveals the main strategies for implementing a value management approach to improve on lean construction methodologies in order to contribute to sustainability implementation and performance improvement. The paper also explores the theories behind value management and the concept of value optimisation within construction.

Keywords:

client value system, customer value management, value management, value, lean construction techniques

1 Introduction

The construction industry has adopted lean techniques to eliminate waste and increase profit due to the success of lean production in the manufacturing industry (Salem *et al* 2005). Most of the work in the early history of lean construction has been dealing with reduction of waste; a little work has been looking at project management principles and even less has addressed the issue of maximising value for the client (Bertelsen 2004).

At present, most construction companies in the UK have started implementing lean construction with the hope of achieving better result, following the ‘Egan Report’ (DETR, 1998) which has strongly influenced the idea of lean thinking in the UK. Lean thinking now seems set to dominate the UK construction industry’s quest to improve quality and efficiency (Green 1999). Several studies have assessed the implementation of lean with respect to reduction of waste but few empirical studies investigated the effect of lean construction techniques in terms of value to the client. The construction industry and its clients need to be aware of the perceived benefits of lean construction on projects to encourage them to employ lean construction techniques on their projects.

Value Management and Value Engineering are techniques for enhancing value within a project by defining what will deliver value in a specific project, engineering a best value solution to meet those defined value parameters, and then delivering a cost effective solution (Egbu et al, 2004).

This paper explores the theories behind Value Management and the concept of value. It is part of an ongoing doctoral study on: the impact of lean construction techniques on sustainable construction.

2 Value Management and Value System

Value Management is considered as an important tool in managing a project. According to Kelly et al (2002), Value Management has been defined as a proactive, creative, problem-solving service. It involves the use of a structured, facilitated, multi-disciplinary team approach to make explicit the client's value system using functional analysis to expose the relationship between time, cost and quality.

Emmitt *et al* (2005) stated that value is the end-goal of all construction projects and therefore the discussion and agreement of value parameters is fundamental to the achievement of improved productivity and client/user satisfaction. Achieving best value in construction has long existed as the aim of clients and contractors. At present, it has become a raised area for drastic performance improvement in the public and private sector (Egbu et al 2004). Supporting this view, Berstelsen (2004) stated that much work remains within the area of value and Value Management including how to maintain and communicate the projects' specific value parameters during the whole project life cycle. The framework developed by Emmitt et al (2005) as shown in figure 1 reveals the 7Cs of value based building process. This shows that the client role is important in the value design stage and to the success of construction projects. OGC (2007) submits that value in its broadest scope is the benefit to the client.

Emmitt et al (2005) view value as an output of the collective efforts of the parties contributing to the design and construction process; which is central to all productivity; and providing a comprehensive framework in which to work. Value must be established before doing anything else. Emphasis is on value creating activities as the initial framework for the entire building process and the reduction of waste in the later value delivery phases.

Figure 1: A value-based building process (source: Emmitt, et.al 2005)

According to Gohil et. al (2010), the concept of value can have many definitions but generally, they are not conflicting. These definitions majorly address "hard" features or elements of values and not the "soft" attributes discussed by Emmitt and Christoffersen (2008). Bruno and Lay (2008) stated that the importance of values is that once it is internalised, it becomes, consciously or subconsciously, a criteria for guiding one's

beliefs. Values exist in relation to the values held by others and are thus not absolute but are in constant transformation. Hence, agreement of an objective best “value” for a group can differ from the individuals’ perception of value (Gohil et. al, 2010). Even though most people have a feeling of what is meant by the term “value”, it seems to be difficult to formulate a common definition (Thyssen et al. 2010). Some definition of value from a range of perspective such as marketing, Lean Thinking, Value Management and customer relation approach are presented in Table 1.

Table 1: Definitions of value

Authors/year of publication	Definition/description/understanding and explanation of value
Woodruff and Gardial (1996)	Value can be considered as the final result of the exchange of negative and positive consequences as perceived by customers
Neap and Celik (1999).	Value can be considered as an innovative concept whose definition includes mainly two parameters: cost and soft measure such as worth, functionality or satisfaction (depending on the expected project out comes)
Weinstein and Johnson (1999)	Value is the satisfaction of customer requirements at the lowest total cost of acquisition, ownership, and use
Lindfors (2000)	Value is the products/services that increase profit, decrease time and cost, and improve quality for the company and generate profit/value for the customer.
Kelly and Male (2001)	Value is defined as the equivalence of an item expressed in objective or subjective units of currency, effort, exchange, or on a comparative scale that reflects the desire to obtain or retain the item.
Womack and Jones (2003)	Value refers to materials, parts or products – something materialistic which is possible to understand and to specify
Kelly (2007)	Value equals to function divided by cost
Buttle (2009)	Value is the customer’s perception of the balance between benefits received from a product or service and the sacrifices made to experience those benefits.

2.1 Client Value System

Construction industry’s procuring clients are largely pursuing innovative approaches to ways in which their projects are planned, designed and delivered to facilitate their business strategies. They are looking for a structured method to manage their project process within the context of their organisation business strategy, and also to work closely with the supply chain to maximise value and achieve continuous improvement in construction performance (Kelly et al, 2002). This has also been put forward by Brimson and Antos, (1999) that value depends on the supply chain synchronisation. This is because the supply chain synchronisation of supplier to organisation to customer is a key to adding value. Zimmerman (2001) widens the theory of intrinsic value in which it is stated that in any value system no parts of the variables are correlated and all variables should have intrinsic value. Value, as defined in Lean Thinking (Womack and Jones 2003), refers to materials, parts or products – something materialistic which is possible to understand and to specify (Koskela 2004).

According to Emmitt *et al* (2005), value may be divided into external and internal value: External value is the clients’ value and the value which the project should end up with, while internal value is the value that is generated by and between the participants of the project delivery team (contractor, architects, designers etc.). In this regard, the concept of understanding value generation during the early stage design phase as a

learning process between the client and the design professionals has been put forward by Green (1999) such that there was a joint understanding of client's value parameters and their realisation in the design.

2.2 Customer Value Management

According to Gale (1994), there are four stages to customer value management: conformance quality stage, customer satisfaction stage, market-perceived quality and value relative to competitor's stage, and quality - a key to customer value management. Creating value that customers can see start from understanding customer needs in a well defined market and results in the overall goal of profitability, growth, and shareholders value.

Various ideas on Value Management have been put forward with emphasis on the initial project stages where the value parameters are specified (Emmit et al 2004). It is very important to understand the construction process as comprising of two distinct processes: value creation and value delivering i.e. Concept and Construction. The client has a set of requirements and budget limit and in the concept phase the challenge is therefore to maximise the value within this financial constraint (Bertelsen, 2004). A comprehensive customer value analysis was presented taking into consideration the seven customer analysis tool. The seven customer analysis tools according to Gale (1994) are:

1. The market-perceived quality profile
2. The relative price profile
3. The customer value map
4. The won/lost analysis
5. A head-to-head area chart of customer value
6. A key events time line
7. A what/who matrix

Bertelsen (2004) stated that manufacturing identifies the market's value parameters and develops the product accordingly, while construction is often creation of unique works. Construction integrates the product development with the actual production for example a flow of work and creation of value as well (Koskela, 2000). A Value Based management approach was proposed by Wandhal (2005) in which the value for the customer is considered as product value and the value for the workers and project participants is termed process value. Value Management is currently only associated with the early stages of projects, focusing on the analysis of functions to achieve the value defined by the customer without diminishing cost and quality (Salvatierra-Garrido et al, 2008).

The aim of Value Management is to optimise the points of view of different participants—from stakeholders to final users— into the process in order to achieve the final goal with minimum resources. "The concept of Value is based on the relationship between satisfying needs and expectations and the resources required to achieve them" (The Institute of Value Management UK, 2011).

2.3 Value Management Strategies

Value Management uses a unique combination of concepts and methods to create sustainable value for both organisations and their stakeholders. Value Management provides a means to define projects clearly and unambiguously in terms of the client's

and the end user's long-term business needs, and provides opportunity for options to be considered. Value Management supports crucial decision-making based upon maximising value (Smith, 2008). According to The Institute of Value Management, UK (2011), some tools and techniques are specific to Value Management and others are generic tools that many organisations and individuals use. The following are some of the main tools and techniques: Brainstorming of Mind Shower, cost benefit analysis, criteria weighting technique, excursion/metaphors, functional analysis system techniques, objectives hierarchy, issues generation and analysis, pair wise comparison, Pareto analysis, process mapping, risk analysis, SCAMPER, stake holder analysis, SWOT analysis, value analysis, and 5W's & H.

In value improvement process, value analysis or producing the FAST model and analyzing functions with the value analysis matrix are the first steps in the process. However, work begins with brainstorming, developing and analyzing potential improvements in the product.

Salvatierra-Garrido et al (2008) concluded that additional research is needed to develop Value Management enabling techniques and procedures.

3 Lean Construction and Value

Koskela (2000) carried out a detailed exploration of the use of the term 'value' and deduced that value can be related to either market value and/or utility value. This view of value is supported by many other researchers as presented in the lean construction (LC) papers (Wandahl and Bejder, 2003). Value Management is described as, "Conceptualization of production (from value viewpoint): As a process where value for the customer is created through fulfilment of his requirements." (Bertelsen and Koskela, 2002). Nonetheless, Koskela (1992) suggested that construction production process should be viewed as transformation of input and outputs, a flow of material and information, and a value generation process. Thus, value creation and generation is the major component of the Transformation-Flow-Value (TFV) of production that was put forward by Koskela (1992). Ballard and Howell (1998) stated that value is generated through a process of negotiation between customer's ends and means. According to Lindfors (2000), value is the products/services that increase profit, decrease time and cost, and improve quality for the company and generate profit/value for the customer. Leinonen and Huovila (2000) mentioned three different kinds of values; exchange value, use value and esteem value. The first two can be translated directly into market value and utility value. The third value has a broader scope than only the product-customer perception. A model for reinforcing the manager's belief is applied by Marosszeky et al (2002), and it is concluded that each organisation tends to view quality from its parochial perspective due to the culture. Figure 2 shows the difference in perception of product and process values.

Figure 2: Difference in perception of values (Source: Wandahl 2002)

3.1 Value Delivery through the Implementation of Lean Construction Techniques

Work flow control through the Last Planner system, Value Stream Mapping (VSM), Just-In-Time (JIT) production and Supply-Chain Management (SCM), and Pokayoke or the Five Why's technique are the most commonly referred lean techniques in construction (Björnfot and Stehn, 2007). The work in lean has focused on the management of value in construction projects by using process tools to identify and minimise uncertainty and improve work flow in production (Emmitt et al 2004). According to Koskela (1992), there are two main processes in a construction project: design process and construction process. Design process is a stage wise refinement of specifications where vague needs and wishes are transformed into requirements, then via a varying number of steps, to detailed designs. Simultaneously, this is a process of problem detection and solving. It can be further divided into individual sub processes and supporting processes. Construction process is composed of two different types of flows: Material process consisting of the flows of material to the site (including processing and assembling on site), and Work processes of construction teams (Lee 1999). Koskela (1992) stated that the processes may be characterized by their cost, duration and the value for the customer. The value consists of two components: product performance and freedom from defects (conformance to specification). Value has to be evaluated from the perspective of the next customer and the final customer. Cost and duration depend on the efficiency of value-adding activities and the amount of non value-adding activities. Several principles that enable of the share of non-value-added activities conducted was summarised by Koskela (2000) as follows: increase output value through systematic consideration of customer's requirements; reduce variability; reduce cycle time; simplify by minimising number of steps; parts the linkages, increase output flexibility; increase process; transparency; build continuous improvement into process; balance flow improvement with conversion improvement; benchmark. Emmitt et al (2004) stated that in design management and lean approaches, craving for value maximisation starts from the initial team composition.

3.2 Challenges of Value Maximisation in Lean Construction Implementation

According to Mok et al (2010), few researches have been conducted pertaining to the improvement of value maximisation in the construction industry. As projects become complex, dynamic, and fast, managing value becomes a challenge in lean construction. Literature has revealed that over the years, some authors have made an approach to this challenge, mostly with an outset in methods found in value engineering or similar disciplines (Bertelsen 2004; Salvatierra-Garrido et al 2008). The creation of this waste

can be prevented by applying lean construction principles. Salvatierra-Garrido et al (2008) stated that more research efforts are needed to better understand the concept of value generation and how to implement it. This is because the major challenge in research dealing with value is the fact that the term itself has escaped a canonical definition. According to Josephson and Saukkoriipi (2005), a Swedish study reports that only about 20 % of performed work is directly value adding, showing a striking rate of pure waste in traditional construction projects. Lean construction considers both construction waste and poor safety as potential wastes that hinder flow of value to the client and should hence be eliminated. Several barriers to the implementation of lean construction have been identified as shown in Table 1. Subsequently, these barriers to the implementation of lean construction will be narrowed down to those challenging maximisation of value to client. Bashir et al (2010) classified these barriers into six different categories: Management issues, financial issues, educational issues, governmental issues, technical issues, and human attitudinal issues.

Table 1: Challenges of Lean Construction Implementation

Authors	Barriers Identified
	-how to come to grips with the specification of desired or required behaviour beyond the task level
Seymour (1999)	-how to articulate, through some kind of representation, what is intended and how it is to be achieved.
Common et al (2000)	- A distinct lack of understanding and application of the fundamental techniques required for a lean culture to exist
Salem et al (2005)	-The unfamiliarity with or misunderstanding of lean concepts and implementation -Cultural barriers in many organisations act as obstacles to change. -Lack of adequate skills and knowledge -Management issues -Government issues such as bureaucracy and instability -Attitude issues such as wrong attitude to change and poor team spirit among professionals -Resources related issues such as lack of basic amenities, equipment, and funding for project.
Olatunji (2008)	-Logistics issues such as delay in delivery and material scarcity -Lack of attentiveness and commitment from top management -Difficulties in understanding the concept of lean construction -Lack of exposure on the need to adopt the lean construction concept -Lack of proper training -Weak communication among clients, consultants, and contractors -Tendency of construction firms to apply traditional management concepts
Abdullahi et al (2009)	-Poor attitude and teamwork -Long implementation period
Mossman (2009)	-Fragmentation -New thinking vs. old habits -Squeezing Middle Management -Low level literacy and computer literacy -Lean education, competing consultants -There's not so practical as a good theory -Fear -Technological barriers -Financial barriers -External barriers
Tourki (2010)	-Internal barriers such as human factor, culture factor, and learning factor

This challenge is taken up by lean construction which has proved to be a valuable philosophy for construction by better meeting customer demands and improving the construction process (Howell, 1999; Ballard and Howell, 2004). Successful implementation of lean has been reported by Emmitt *et al* (2005) and a number of definitions have been suggested which may be used generally for discussing and implementing value through lean construction.

4 Value Management, Lean Construction and Sustainability

Value Management and lean construction have been seen as the way forward to improve delivery of value to clients and building users (Emmitt et al, 2005). Value Management seeks to maximise project value within time, cost and quality for the customers with an item that satisfies the basic function they require at the best value for the money spent. The term "Value Management" encompasses both Value Engineering and Value Analysis. However, it should be noted that improving whole-life project value sometimes requires extra initial capital expenditure (OGC, 2007).

Value Management is about enhancing value and not about cutting cost, although this may be a by-product. The principles and techniques of Value Management aim to achieve the required quality at optimum whole-life cost during the process of developing a project. The principles centred on the identification of the requirements that will add demonstrable value in meeting the business need (OGC, 2007). The idea of creating value is mainly focused on value engineering to ensure that the value specified will be delivered to the client while the cost is kept as low as possible (Bertelsen, 2004). Lean construction practices is intended to complement value engineering and therefore, do not compete with value engineering. Lean construction aims at maximising value and minimising waste (Lehman and Reiser 2004).

According to Senaratne and Wijesiri (2008), the core principles of lean construction are elimination of non value adding flow activities and making conversion activities more efficient. Leong and Tilley (2008) carried out a study to explore the notion of measuring next customer needs as part of a lean performance measurement strategy in order to try to achieve end user customer satisfaction. It was concluded that the failure to implement appropriate measures is common within the industry and can lead to not only wrong conclusions or behaviour, but also poor decision making due to inadequate information. Furthermore, they stated that in order to drive behaviour towards value through the elimination of waste, the industry needs to understand the principles of systems thinking and variation and implement appropriate measures to identify where system improvements can be made.

Lean thinking places 'optimising the total value' instead of 'minimising the cost' as the main goal. Within lean, cost cutting has to be seen in perspective of eliminating non value adding activities (Womack and Jones, 2003). Salvatierra-Garrido et al (2008) stated that when defining value, there are different disciplines such as the Lean Thinking and Value Management, which aim to incorporate value in the process of developing a successful final product and satisfying user's real need. They further stated that integrating Value Management and Lean Thinking at the early stage of social housing project in Chile is proposed as the solution to achieving better results in projects where cost, quality and social responsibility are drivers. Lean Thinking in construction focuses on process tools to identify and minimise uncertainty and hence improve workflow in production (Emmitt et al., 2004).

Similarly, Sustainability is about securing our long-term future, by following the four main tenets of sustainable development which are: protection of the environment, prudent use of scarce resources, promotion of access to services for the benefit of all, and production of a healthy local economy, including high levels of employment (Royal Institution of Chartered Surveyors, 2009). According to MaSC (2002), Sustainability

promotes a balanced approach by taking account of the need to continue in business, but does not seek profitability at the expense of the environment or society's needs. Thus, sustainability concerns protecting environmental quality, enhancing social prosperity and improving economic performance (Addis and Talbot, 2001). According to the members' report of the workshop organised by Construction Productivity Network (2009), lean and sustainability concepts are basically compatible through waste minimisation. Cost savings from waste reduction can provide both real added value to the business as well as paying for sustainability actions.

According to Al-Yami and Price (2006), it is highly beneficial to adapt Value Management for use in uplifting sustainable construction principles so as to implement in the early stages of building projects. As such, there is need for a change of thinking from clients, operators and managers in the construction industry during implementation of sustainable construction principles in a project from short term to future impact; shareholders to stakeholders; product to service; and cost to value. These changes, according to Hayles (2004), are the key priorities of a Value Management project. Al-Yami and Price (2006) concluded that soft Value Management is an essential tool to be used in identifying and developing the briefing of a building project to reduce negative impacts on the environment, assure optimised whole life cost of a project, and satisfy good indoor environment in the project thus achieving the aims of sustainability.

5 Discussion

The perception of value to stakeholders in construction differs but Value Management, through the implementation of lean principles, resolves differing priorities to meet the expectation of stakeholders. So, lean construction is not only concerned with minimising waste but it directly contributes to value creation. Even though the adoption of lean construction principles seem to lay a foundation for Value Management, concerted effort should be made to further emphasise Value Management approach to improve on lean construction methodologies in order to contribute to sustainability implementation and performance improvement. Thus, there is need to determine the linkage between Value Management and lean construction, priorities of lean construction, and how implementation of lean construction principles leads to value maximisation.

6 Conclusion

Construction projects are intrinsically prone to changes and innovation. They are understood in theory to deliver value to customer/client. Currently, lean construction loses sight of the innovative and ingenious dimension of Value Management and the effect of lean construction techniques on sustainable construction in terms of value to the client. The suitability of lean construction to promote sustainable construction in terms of value to the client is discussed. The main strategies of Value Management approach to improve on lean construction methodologies in order to contribute to sustainability implementation and performance improvement are been explored, thus reflecting the concept of value maximisation at the early stage of the project.

Integrating lean construction principles in Value Management is essential for the optimisation of value for end users, construction clients and all the stakeholders as the

process and the product value is of utmost importance to them. When lean construction and Value Management are effectively integrated they form an intrinsic tool to be used for project briefing and development. This paper is part of an ongoing research which aims to examine the impact of lean construction on sustainable construction in order to further promote the understanding of lean construction principles and facilitates its adoption and implementation as regards value generation, maximisation, and delivery within the construction industry. This integration will impact on the three dimension of sustainability in a project: environmental, social and economic. The ongoing research will proceed to identify the priorities of lean construction and sustainability and also identify the success factors and barriers to the implementation of lean construction.

Abstract:

Risk is endemic in construction projects and previous studies suggest that variability between contract sum and final account was as a result of risk occurring during the project's life. This study uses the risk theory to uncover the significant risk variables thought to impact the construction phase with attendant impact on the out turn cost of construction projects. The significant risk variables were then used to develop models for assessing risk impacts on the variability between contract sum and final account. A two-stage approach was adopted in data collection. The first was an online questionnaire survey of risk factors thought to impact the variability between contract sum and final account. A ranking of the mean score of the survey responses enabled the significant risk factors to be determined. The second stage of the data collection involved collection of data regarding contract sum and final account from recently completed projects. Quantity Surveyors who worked on the projects were then requested to score the extent of occurrence of the identified significant risk factors on a Likert-type scale. The pair of data set obtained was then used to model risk impacts on the variability between contract sum and final account using artificial neural network modelling method. The result obtained was promising and the developed models could help the construction contractor to predict the likely impacts of risk occurring at project execution phase on out turn construction cost.

Keywords:

artificial neural network, contract sum, final account, risk variables, risk modelling

1 Introduction

It is widely acknowledged that the construction industry is both more risky and uncertain than most other industries. This makes the subject of risk a very important factor to be considered in construction projects. Change is inevitable in construction and if it is not dealt with properly it can have detrimental effects on time, cost, scope and quality targets. Smith (1999) points out that change cannot be eliminated but, by applying the principles of risk management, practitioners are able to improve the effective management of this change. According to Smith (1999) risk exists when a decision is expressed in terms of a range of possible outcomes and when known probabilities can be attached to the outcomes.

Odeyinka *et. al.* (2009) investigated the budgetary reliability of bills of quantities (BOQ) in building project procurement and concluded that the difference between the budgeted cost and the final cost incurred differed greatly depending on project type. The variation between the budgeted cost of a project in the BOQ and the actual cost incurred was evaluated using secondary data obtained from recently completed traditionally procured building projects in Northern Ireland. The study concluded that with housing projects the percentage deviation from the BOQ was between -3.42% and +3.85%. With educational projects the percentage deviation was found to be between -3.69% and +17.05%. The range in regards to commercial projects is between -19.94% and +19.92%. When refurbishment projects were looked at, the percentage deviation was found to be between -10.72% and +36.90%. This finding shows that there can be a huge difference between the contract sum and the final account.

According to Flanagan and Tate (1997) clients want certainty of price, projects constructed within budget and no surprises. According to them, the budgeted cost decided at the pre-contract stage of any construction project forms the basis of the contract sum. As this is the budget established for the project it is not expected to be exceeded. According to Flanagan and Tate (1997) a contingency sum should be included in the cost budget to cover unforeseen items and all eventualities which can occur during the construction of a project. This should ensure the completion of all projects within the cost budget. However according to Winch (2010) and Walker (2002) there is much evidence in construction management literature that would indicate that it is very difficult to find a project in which the initial contract sum is not exceeded at completion.

According to Winch (2010), risk is inherent in construction from the inception to the completion stages of a project's life. According to him, the less information is available at the inception of a construction project, the higher the level of risks and uncertainties. Whilst it is a known fact that the risk factors inherent in a construction project are responsible for the observable deviation between the tender sum and final account, how these risk factors combine to impact the project cost is the concern of this study. The overall aim of the research is to model risk impacts on the variability between contract sum and final account.

2 Literature Review

According to Baloi and Price (2001) risk can mean different things to different people and therefore the concept of risk can vary according to individual's viewpoint, attitudes and experience. For example; engineers, designers and contractors may be more likely to view risk from the technological perspective whereas lenders and developers tend to view it from an economic and/or financial point of view, etc. Baloi and Price (2001) therefore concluded that risk is in general seen as an abstract concept which is very difficult to measure. Smith (1999) defines risk as a decision which has a range of possible outcomes and that a known probability can be attached to each of these potential outcomes. Akintoye and MacLeod (1997) state that risk in construction has come to attention as a very important aspect to be considered because of the occurrence of cost and time overruns in construction projects.

Baloi and Price (2001) maintained that risk within construction projects could be defined as the likelihood of a detrimental event occurring to the project. Similarly,

Wideman (1986) defines project risk as the chance of certain occurrences adversely affecting project objectives. However, Chapman (2001) argued that this definition does not take into consideration, the possibility of a positive outcome and so he defined risk as an event, which should it occur, would have a positive or negative effect on the achievement of a project's objectives. That view was also supported by the Project Management Institute (2008).

Chapman's (2001) definition was also supported by Heale (1982) who also argued that risk is an exposure to either economic loss or gain due to involvement in the construction process. Similarly, Winch (2010) argued that in statistical terms risk refers to unexpected events where the outcome is either to the benefit or detriment of the decision maker. However, he also goes on to say that in common practice risk is only used to refer to the probability of a detrimental effect, with the word reward being used to signify the probability of a beneficial event occurring.

According to Flanagan and Tate (1997) the budgeted cost established at the pre-contract stage forms the basis of the contract sum, this is the amount established for the entire project and it is not expected to be exceeded. In addition, Flanagan and Tate (1997) maintained that the budgeted cost should include for both foreseen and unforeseen costs that are needed for the completion of the project's objectives. According to Ashworth and Hogg (2002) all the planning and decision making by both the contractor and the client depends upon the budgeted cost and so the budgeted cost is expected to be accurate in order to avoid cost overruns.

According to Potts (2008), most clients work within tight pre-defined budgets, which are usually part of a larger scheme. If a budget is exceeded, the whole scheme may fail. Pre-contract estimating produces the original budget and this forecasts the likely expenditure for the client. He goes on to say that this budget should be used positively in order to make sure that the design stays within the scope of the original scheme. According to Magnussen and Olsson (2005) the observed difference between the contract sum and final account is due to factors which are not only hard to predict but difficult to manage. Morris and Hough (1991) state that cost overruns are caused by circumstances which are outside of the project's area of control. According to them, many projects overrun on cost because of price escalation, government action, strikes etc. Therefore an important issue is the ability to predict such factors and the impact they will have on the project.

Fong (1987) and Odeyinka *et. al.* (2006) asserted that it is generally recognised that those within the construction industry are continually faced with a variety of situations involving many unknowns, unexpected, frequently undesirable and often unpredictable factors. These factors according to Fong (1987) include timing schedule slippage of the project tasks, technological issues, people-oriented issues, finance, managerial and political issues. The concern of this study is the variability between contract sum and final account. The conjecture of the study is that risk is responsible for the observed variability. This study therefore explores the cognitive model of risk (Winch, 2010) to uncover the underlying risk variables impacting the variability between contract sum and final account. Using JCT (2005), some of the risk factors identified include; variations by the client, change in design by client, change in scope of works, unexpected site conditions and change in design by the Architect. Others include; problems arising due to client's lack of experience, inadequate specification, extremely

competitive tender, third party delays, defects in design, delay in resolving disputes, delay in nominated/ named material supplier, underestimation of quantities, local concerns and requirements, contract document conflicts, project funding problems, ambiguous contract terms, loss or damage by fire or flood.

3 Research Methodology

A two-stage approach was adopted in data collection. The first was an online questionnaire survey of risk factors thought to impact the variability between contract sum and final account. Data sets for the first stage were sourced from UK based Private Quantity Surveyors (PQS), Contractors' Quantity Surveyors, Architects and Project Managers. A stratified random sampling approach was adopted whereby the sampling frame was drawn from available databases such as the Royal Institution of Chartered Surveyors' (RICS) Find a Surveyor Service, the Royal Institute of British Architects (RIBA) database and Constructing Excellence in Northern Ireland (CENI) database. A total of 348 potential respondents were emailed enquiring whether they were willing to complete an online questionnaire for the purpose of this research. Of these 62 replied that they were willing to complete a questionnaire. In all, 43 completed responses were received, which translates to a response rate of 69.35%. The designation of the respondents is shown in Table 1 with mean years of experience of 26.05 and standard deviation of 12.17. A project-by-project approach was adopted in the survey and the location of the surveyed projects is shown in Table 2. About 60% of the projects surveyed were new build whilst about 40% were refurbished building projects as shown in Table 3. Using the cognitive theory of risk, a total of 18 risk factors thought to potentially influence the variability between contract sum and final account were identified from literature and also from discussion with construction professionals. Using a two-dimensional scaling, respondents were requested to score on a Likert –type scale of 0-5, the extent of the identified risk factors occurring and their perceived impacts in case of occurrence. The Likert-type scale used for the two-dimensional scaling questionnaire was defined as follows: 0 – no likelihood of occurrence and no impact, 1 – very low occurrence and very low impact, 2 – low occurrence and low impact, 3 – medium level of occurrence and medium impact, 4 – high level of occurrence and high impact, 5 – very high level of occurrence and very high impact. This then gives the measuring scale the property of an interval scale, which makes the collected data suitable for various statistical analyses.

Table 1: Designation of Respondents

Designation	Frequency	Percent	Cumulative Percent
Architect	11	25.58	25.58
Client's QS	21	48.84	74.42
Contractor's QS	6	13.95	88.37
Project Manager	5	11.63	100.00
Total	43	100.00	

Mean years of experience: 26.05 and Standard deviation: 12.17

Table 2: Project Location

Location	Frequency	Percent	Cumulative Percent
England	20	46.51	46.51
Northern Ireland	6	13.95	60.47
Scotland	2	4.65	65.12
Wales	15	34.88	100.00
Total	43	100.00	

Table 3: Type of Building Surveyed

Building Type	Frequency	Percent	Cumulative Percent
New build Commercial	7	16.28	16.28
New build industrial	4	9.30	25.58
New build public & community building	4	9.30	34.88
New build contract house building	5	11.63	46.51
New build institutional building (Education & Health)	6	13.95	60.47
Refurb commercial building	4	9.30	69.77
Refurb public & community building	7	16.28	86.05
Refurb contract house building	4	9.30	95.35
Refurb institutional building	2	4.65	100.00
Total	43	100.00	

Responses to the questionnaire survey were analysed using the mean analysis, which were subsequently ranked in order to determine relative importance of the risk factors considered. The mean score is determined as follows:

$$MeanScore = \frac{5n_5 + 4n_4 + 3n_3 + 2n_2 + 1n_1 + 0n_0}{(n_5 + n_4 + n_3 + n_2 + n_1 + n_0)} \quad (\text{Equation 1})$$

Where: n_0, n_1, n_2, n_3, n_4 and n_5 are the number of respondents who scored the responses as 0, 1, 2, 3, 4 and 5 respectively.

Many risk management researchers as stated earlier viewed risk as the probability that cost, schedule or technical performance of a system goes wrong combined with the consequences of these aspects going wrong. With this view, they argued that risk could be measured using the following formula:

$$R = P * I \quad (\text{Equation 2})$$

where: R = the degree of risk, P = probability/extent of occurrence of a risk factor; I = the consequence or perceived impact on a project.

Akintoye *et. al.* (2001) and Carter *et. al.* (1994) referred to this as the risk exposure or expected value (EV) while Tweeds (1996) referred to it as average risk estimate. This method of risk measurement has a well-established place in decision theory domain and has been employed in this study to determine significant risk factors.

The second stage of the data collection involved collection of contract sum and final account data from recently completed projects. Project Quantity Surveyors who worked on the projects were then requested to score the extent of occurrence of the identified significant risk factors on a Likert-type scale. The pair of data set obtained was then used to model risk impacts on the variability between contract sum and final account using artificial neural network modelling method.

4 Findings and Discussion

The summary of the mean response analysis result of construction professionals' perception of the extent of occurrence of the identified risk factors and their perceived impacts is shown in Table 4. Table 4 shows the ranked mean response analysis along the classifying categories of 'all projects surveyed', 'new build projects' and 'refurbishment projects'. The mean score analysis of the 'overall extent of risk occurrence' ranges from 1.07 to 3.26. This suggests that the overall extent of risk occurrence ranges from very low to medium level. The mean score analysis of the perceived impacts of risk occurrence ranges from 1.05 to 3.05 which also indicates that the overall risk impacts range from very low to medium level of impact. The same trend was observable for 'new build' and 'refurbishment' projects.

Using Equation 2, the degree of risk was calculated for 'overall', 'new build' and 'refurbishment' projects surveyed. The results of the calculated degree of risk are listed in Table 4. It is interesting to see that the ranking of the degree of risk for the three classifying categories follow the same order. Using risk-rating rules as suggested by the Project Management Institute (2008), a risk extent/ impact matrix was devised to determine the significant risk factors to focus on. From the list in Table 4, the top 5 risk factors were selected as those to focus attention on for modelling purposes.

It is actually not a surprise that the top 5 risk factors, namely; 'variations by the client', 'change in design by the client', 'changes in scope of works' and 'unexpected site conditions' and 'change in the design by the Architect' all ranked high in terms of extent of occurrence and impacts. This is because these are risk factors which are difficult to predict in advance in most large scale and one off projects. The majority of these risk factors are design-related and at the pre construction phase, the quality of the design will be as good as the design information available. However, during the construction phase, as more information are available, Architects may see the need for changes to the original design, clients who are also getting the grasp of construction realities may also wish to suggest variations so as to ensure that their objectives are met. In some cases, they may also suggest changes to the scope of works. Since contract sum is based on pre construction information available, it is therefore not a surprise that some variability exists between the contract sum and the final account.

4.1 Model Development

In order to model risk impacts on the variability between contract sum and final account, data were sourced from some recently completed building projects. The data

set collected include contract sum, final account, project type and whether new build or refurbishment. In order to obtain reliable models, the data sets were categorised according to building type and whether new build or refurbishment projects. Variations between the contract sum and final account were then computed for each category. Using the identified significant risk factors determined in the previous section, the project Quantity Surveyors who worked on the selected projects were asked to score on a Likert-type scale, the extent of occurrence of the identified significant risk factors. These set of data pairs were then used to develop models to predict risk impacts on the variability between contract sum and final account.

Two approaches were considered in model development, the traditional approach, using multi linear regression (MLR) and the artificial neural network (ANN) approach. The results obtained using MLR was not promising; as such modelling efforts were concentrated on using the ANN approach. According to Ogunlana et. al (2001) and Masters (1994), neural network based modelling process involves five main aspects. These are (1) data acquisition, analysis and problem representation; (2) architecture determination; (3) learning process determination; (4) training of the network; and (5) testing of the trained network for generalisation evaluation.

Since there are 5 significant risk factors which constitute the input variables, this suggests that the neural network architecture will have 5 input nodes. As there is only one output value of variation between contract sum and final account, this suggests that the neural network will have 1 output node. After a number of trials and errors, the network was found to stabilise with 2 layers of 5 hidden nodes each. Thus, the model employed a 5- 5- 5- 1 back propagation architecture as shown in Fig 1.

Table 4: Ranking of extent of risk/ impact and degree of risk for new build and refurbishment projects

Risk factors	Overall risk extent mean	Overall risk impact mean	Overall degree of risk	Rank	New build risk extent mean	New build risk impact mean	New build degree of risk	Rank	Refurb risk extent mean	Refurb risk impact mean	Refurb degree of risk	Rank
Variations by the client	3.26	3.05	9.93	1	3.32	3.08	10.23	1	3.17	3.00	9.51	1
Change in design by client	3.16	2.98	9.41	2	3.24	2.92	9.46	2	3.06	3.06	9.35	2
Change in scope of works	2.74	2.86	7.84	3	2.6	2.68	6.97	3	2.94	3.11	9.15	3
Unexpected site conditions	2.21	2.26	4.99	4	2.16	2.28	4.92	4	2.28	2.22	5.07	4
Change in design by Architect	2.09	1.95	4.08	5	2.12	1.80	3.82	5	2.06	2.17	4.46	5
Problems arising due to client's lack of experience	2.07	1.91	3.95	6	2.16	1.88	4.06	6	1.94	1.94	3.77	6
Inadequate specification	2.05	1.77	3.62	7	2.08	1.64	3.41	7	2.00	1.94	3.89	7
Extremely competitive tender	1.98	1.70	3.36	8	2.08	1.72	3.58	8	1.83	1.67	3.05	8
Third party delays	1.93	1.67	3.23	9	1.88	1.84	3.46	9	2.00	1.44	2.89	9
Defects in design	1.86	1.65	3.07	10	1.84	1.72	3.16	10	1.89	1.56	2.94	10
Delay in resolving disputes	1.79	1.65	2.96	11	2.2	1.60	3.52	11	1.22	1.72	2.10	11
Delay in nominated/ named material supplier	1.72	1.60	2.76	12	1.84	1.48	2.72	12	1.56	1.78	2.77	12
Underestimation of quantities	1.65	1.49	2.46	13	1.64	1.60	2.62	13	1.67	1.33	2.23	13
Local concerns and requirements	1.51	1.47	2.21	14	1.48	1.40	2.07	14	1.56	1.56	2.43	14
Contract document conflicts	1.4	1.42	1.99	15	1.48	1.56	2.31	15	1.28	1.22	1.56	15
Project funding problems	1.35	1.37	1.85	16	1.52	1.48	2.25	16	1.11	1.22	1.36	16
Ambiguous contract terms	1.28	1.26	1.61	17	1.4	1.36	1.90	17	1.11	1.11	1.23	17
Loss or damage by fire or flood	1.07	1.05	1.12	18	1.04	1.00	1.04	18	1.11	1.11	1.23	18

As project data were collected in different building project types, different models were developed for different project types. The one reported in this paper is the one developed for new build commercial building projects. In all, 19 data sets were collected from commercial building projects. Out of these, 12 data sets were used for training the ANN. After the network was found to have stabilised, it was used to predict the variability between the contract sum and final account for the remaining 7 data set not used for network training.

Table 5 shows the model validation results. Using absolute deviation measure and percentage absolute deviation measure, the Table shows that the difference between the predicted variation and actual variation ranges from 0.2% and 6.5%. Given the limitation of the available data set, the accuracy level of the model is very promising. With more data available, the accuracy level of the ANN model will also improve.

Table 5: Modelling validation results

Project No.	Actual % variation	Predicted variation	absolute deviation	% absolute deviation
1	0.106	0.156	0.050	5.0
2	0.093	0.044	0.049	4.9
3	0.270	0.240	0.030	3.0
4	0.017	0.015	0.002	0.2
5	0.041	0.106	0.065	6.5
6	0.131	0.094	0.037	3.7
7	0.104	0.131	0.027	2.7

5 Conclusion and Further Research

This study has attempted to model risk impacts on the variability between contract sum and final account. Using 18 risk factors derived from literature and from discussion with construction professionals, data were collected on a Likert-type scale using a two-dimensional scaled questionnaire. Data collection was on a project by project basis from different traditionally procured project types, including new and refurbished commercial, industrial, contract house building and industrial buildings. Data analysis was carried out using a mean response analysis and ranking of the mean scores. Further analysis was done using the degree of risk calculation, a procedure which is well established in risk and decision theory.

Fig. 1: Artificial Neural Network Modelling Architecture

Within the limitation of the data collected, it can be concluded that the significant risk factors impacting the variability between tender sum and final account relate to the level of design information or lack of it at the pre construction stage. Those significant risk factors include ‘changes in design’, ‘variations by the client’, ‘changes in scope of works’ and ‘unexpected site conditions’. This finding corroborates Winch’s (2010) assertion that the more information is available at the pre construction stage, the less risk to contend with during construction.

Using the 5 identified significant risk factors, namely; ‘variations by the client’, ‘change in design by the client’, ‘changes in scope of works’, ‘unexpected site conditions’ and ‘change in the design by the Architect’ together with the variability between contract sum and final account, a predictive model was developed using ANN. The validation results from testing the developed model showed that the difference between the predicted variation and actual variation ranges from 0.2% and 6.5%. Given the limitation of the available data set, the accuracy level of the model is very promising. With more data available in future research, the accuracy level of the ANN model will also improve. Future research could also involve the exploration of the risk theory in other procurement methods.

United Kingdom

Email: S.Ruddock@salford.ac.uk; L.Ruddock@salford.ac.uk

Abstract:

For an assessment of the productivity performance of construction at the industry level, the quality of any analysis can be improved by the availability and use of detailed data on the basic components of the industry's production function. The EU KLEMS Growth and Productivity Accounts comprise a data set that provides a rich source of information on the sources of growth by industry, one of which is the construction industry (ISIC 45), since the 1970s for European Union countries and other major economies. The database allows a breakdown of factor inputs by the categorisation of capital inputs into asset types and labour inputs into components such as skill levels to provide more precise measurement of sources of growth at industry level. The UK construction sector forms the focal point of the analysis but some comparisons are also made with the construction industries of other countries. The results of the analysis provide evidence of a steady increase in the growth of ICT and improved labour skills usage and a relatively high rate of total factor productivity for the UK construction industry.

Keywords:

growth, performance, productivity

1 Introduction

Over recent decades, there have been numerous attempts to model and measure productivity in the construction industry focusing on a multi-factor productivity approach and the measurement of total factor productivity (TFP) but such studies of industry level productivity performance assessment have been particularly hampered by the lack of availability of appropriate data on the composition of output and inputs at the meso-level. In the context of the construction industry, Arditi and Mochtar (2000) identified TFP as the definition of productivity that should be used by policy-makers to determine policy and evaluate the state of the sector. Other researchers have derived a variety of means of estimating TFP. For example, Xue et al (2008) used DEA-based indices to measure construction industry productivity in China; Li and Liu (2010) used a Malmquist index method as a decomposition technique to estimate the TFP of the Australian construction industry and analyse the factors affecting technological change in the industry; Tan (2000) and Zhi et al (2010) undertook measurement of TFP for the Singapore construction industry.

However, the problems of data provision are not just issues for the construction industry. The methodology to derive multifactor productivity growth rates has been firmly established since the work of Jorgenson et al (1987) but in practice it has been rarely applied comprehensively. In terms of international data services, the OECD and the Groningen Growth and Development Centre maintain multi-factor productivity series for OECD economies at the macro-level but, to permit international comparisons, the main bottleneck has been the lack of available statistics on the composition of labour and capital at the industry level for a sufficient number of countries. As a result, researchers undertaking international industry productivity comparisons have resorted to cruder methods of output, inputs and TFP measurement, mostly based on national accounts data, the OECD Structural Analysis (STAN) database and its predecessor the International Sectoral Database (ISDB). These databases provide industry level series on output, aggregate hours worked and aggregate capital stock for a limited group of countries and years, while ignoring changes in the composition of factor inputs.

The EU KLEMS Growth and Productivity Accounts (EU KLEMS, 2011) now provide a set of data that provides a rich source of information on the sources of growth by industry and country in the European Union and other major economies. The database is constructed from national accounts and supplementary official statistics and, using growth accounting techniques, allows growth analysis of specific industries within economies as well as divergence across economies. To analyse the causes of changes in growth and productivity rates for an industry, a detailed breakdown of factor inputs and more precise measurement of the sources of growth at industry level is important. Specifically, the categorisation of capital inputs into asset types and labour inputs into components are essential steps towards a more adequate assessment of the growth sources and measures of TFP growth.

Labour input measures in the EU KLEMS Accounts take account of changes in the composition of the labour force and capital input measures include the effects of the rapid shift in investment towards Information and Communications Technology (ICT) assets in recent years. On this latter aspect, Ruddock (2006) reported that the issue of efficiency gains from the use of ICT in the construction industry could only be fully understood if measurement of usage could be improved.

2 EU KLEMS GROWTH AND PRODUCTIVITY ACCOUNTS

The EU KLEMS Growth and Productivity Accounts database was first released in 2007 and subsequently updated in 2008 and 2009. It is the result of a European Commission funded project to analyse productivity in the European Union (EU) at industry level. The purpose of the database is to: ‘ .. support empirical and theoretical research in the area of economic growth, such as study of the relationship between skill formation, investment, technological progress and innovation on the one hand, and productivity, on the other’ (Timmer et al, 2007a, p71).

The Accounts include measures of output, employment, capital formation and TFP at the industry level for EU member states. Generally, data for 1970 onwards is available for the EU-15 (member states as of 1 January 1995) and from 1995 onwards for the EU-25 (member states as of 1 May 2004). Additionally, the database also provides similar accounts for Australia, Japan, South Korea and the USA.

The variables covered in the series in the database fall into three categories:

Firstly, basic variables necessary to construct single productivity measures such as labour productivity, including volume and price series of output and intermediate inputs and volumes and prices of employment. Secondly, growth accounting variables, which are of an analytical nature and cannot be directly derived from published national accounts data without additional assumptions. These include series on capital services, labour services and TFP. The construction of these series is based on a theoretical model of production (O'Mahoney and Timmer, 2009 provide a full explanation of the model). Finally, additional series of data on inputs by category, such as measures of ICT capital and non-ICT capital and various labour characteristics are provided.

2.1 Growth accounting

The data series incorporate measures of output and input growth and derived variables and can be used to consider productivity growth for cross-national comparisons, inter-industry comparisons or for individual industries over time. The variables are organised around growth accounting methodology, which provides a clear conceptual framework, within which the interaction between variables can be analysed in a consistent way. Based on the methodology of Jorgenson and Griliches (1967) and further developed by Jorgenson et al (2007), the growth accounts allow the absolute and relative importance of labour, capital and intermediate inputs to growth to be measured and the derivation of multi-factor productivity measures to indicate the efficiency with which inputs are being used in the production process.

2.2 TFP as a measure of efficiency

Under strict neo-classical assumptions, TFP growth measures disembodied technological change but, in practice, TFP is derived as a residual and includes a host of effects such as improvements in allocative and technical efficiency, changes in returns to scale and mark-ups, as well as technological change proper. All these effects can be broadly summarised as “improvements in efficiency” (Timmer et al, 2007a), as they improve the productivity with which inputs are being used in the production process.

When used in industry comparisons across countries, measures of TFP provide an indication of relative levels of the efficiency of input use between that industry in different countries - TFP levels being measured as the difference in output when differences in all inputs have been accounted for. Differences in TFP levels can be interpreted as differences in the level of disembodied technology, where technology is defined narrowly as level differences in the production functions in different countries. TFP does not, for example, include technology differences that are embodied in the use of capital goods. However, this interpretation of TFP levels is only true under a stringent set of assumptions including an identical production function, constant returns to scale, competitive markets and technical and allocative efficiency. Moreover, input measures must adequately reflect differences in adjustment costs, cyclical effects and input quality between countries (See Schreyer and Pilat (2001) for further discussion).

3 INDUSTRY LEVEL GROWTH ACCOUNTING USING EU KLEMS DATA

3.1 Growth Accounting methodology

Based on the work of Jorgenson and Griliches (1967), the growth accounting framework utilises production possibility frontiers where industry gross output is a function of inputs indexed over time. Output growth can be expressed as a (cost share) weighted growth of inputs and technological change using a translog functional form (O'Mahoney and Timmer, 2009). This means that the production function for an industry is given by:

$$Y = f(X, L, K, T)$$

where Y = gross output, X = an index of intermediate inputs, L = an index of labour service flows, K = an index of capital service flows and T = time.

3.2 Factor inputs

Input and output measures from the UK EU KLEMS database can be used for levels estimations (Timmer et al, 2007a). The share of each input in the value of output under growth accounting assumptions equals total cost. The contribution of each input to gross output growth is found by multiplying its share by its growth rate.

The capital and labour service indices derived in the EU KLEMS database are used in fixed effects and first differences estimations.

TFP indicates the efficiency with which inputs are being used in the production process and is an important indicator of technological change. Under the assumptions of competitive factor markets, full input utilization and constant returns to scale, the growth of output in an industry can be expressed as the (compensation share) weighted growth of inputs and TFP (denoted by A):

$$\Delta \ln Y = v_x \Delta \ln X + v_l \Delta \ln L + v_k \Delta \ln K + \Delta \ln A$$

Where $\Delta \ln X$, $\Delta \ln L$ and $\Delta \ln K$ are the growth rates of intermediate inputs, labour services and capital services respectively; v_x , v_l and v_k indicate the respective shares of intermediate inputs, labour services and capital services respectively in total gross output averaged over two years and $v_x + v_l + v_k = 1$. Each of the three input elements on the right-hand side therefore indicate the proportion of output growth accounted for by growth in the three inputs.

Accurate measures of labour and capital input are based on a breakdown of aggregate hours worked and aggregate capital stock into various components. Hours worked are cross-classified by various categories to account for differences in the productivity of various labour types, such as high- versus low-skilled labour. Similarly, capital stock measures are broken down into stocks of different asset types. Short-lived assets like computers have a much higher productivity than long-lived assets like buildings, and this is reflected in the capital input measures. The contribution of intermediate inputs is broken down into the contribution of energy goods, intermediate materials and services.

The EU KLEMS database makes it possible to take into account changes in the composition of the labour force and the use of capital services, so that TFP is a proxy for technical change.

3.3 Measurement of labour services

An important feature of the database is the breakdown of the labour input data into different components. There may be considerable differences in the productivity levels of, for instance, low-skilled and high-skilled workers. If measures of labour input take the heterogeneity of the labour force into account in analysing productivity, the contribution of labour to output growth can be better measured.

In the accounts, the term for the labour input measures is *labour services*, as they allow for differences in the amount of services delivered per unit of labour in the growth accounting approach. Based on the assumptions that the flow of labour services for each labour type is proportional to hours worked and workers are paid their marginal productivities, an index of labour services (input L) is given by:

$$\Delta \ln L = \sum v_{li} \Delta \ln H_{li},$$

Where $\Delta \ln H_{li}$ indicates the growth of hours worked by labour type i and weights are given by the average shares of each type in the value of labour compensation. In this way, aggregation takes into account the changing composition of the labour force. The database provides a break-down of the labour into categories based on skill level, gender and age group (providing eighteen labour categories in total). This means that labour composition effects can take account of the effects of factors such as a shift in the share of hours worked by low-skilled workers compared to high-skilled workers.

3.4 Measurement of capital services

For the capital input, a feature of the database is the categorisation of capital assets.

Investment series by asset type and by industry come from series obtained from national statistical institutes, allowing for a detailed industry-by asset analysis. An important distinction is that made between ICT assets (office and computing equipment, communication equipment and software) and non-ICT assets (transport equipment, other machinery and equipment, residential buildings and non-residential structures). Quality-adjusted investment deflators for ICT assets are used based on a harmonisation procedure suggested by Schreyer (2001). The real investment series are used to derive capital stocks through the accumulation of investment into stock estimates using the perpetual inventory method and the application of geometric depreciation rates. Then capital service flows are derived by weighting the growth of stocks by the share of each asset's compensation in total capital compensation as follows:

$$\Delta \ln K = \sum v_{kj} \Delta \ln S_{kj}$$

where $\Delta \ln S_{kj}$ indicates the growth of the stock of asset j and weights are given by the average shares of each asset in the value of total capital compensation. In this way, aggregation takes into account the widely different marginal products from the heterogeneous stock of assets.

The weights are related to the user cost of each asset. The user cost approach is crucial for the analysis of the contribution of capital to output growth. This approach is based on the assumption that marginal costs reflect marginal productivity.

4 ANALYSING THE PERFORMANCE OF THE CONSTRUCTION INDUSTRY USING THE EU KLEMS DATA FILES

The EUKLEMS Growth and Productivity Accounts provide data over a period from the 1970s to 2007 for thirty countries covering forty sectors, one of which is the construction industry (ISIC 45). The database enables inter-industry comparisons to be made between the construction industry and other sectors of the economy in addition to inter-country comparisons.

The analysis in this section focuses on value-added as the basis for an assessment of the performance of the industry. Analogous to the breakdown of gross output growth into its constituent input growth components, value added growth can be decomposed to capture the contribution of inputs and TFP growth as:

$$\Delta \ln VA = w_l \Delta \ln L + w_k \Delta \ln K + \Delta \ln A$$

Where VA = value added and w_l and w_k indicate the share of labour and capital respectively in value-added.

As indicated previously, the contribution of capital services to value added growth can be split into the separate contributions of ICT capital and non-ICT capital.

The contribution of labour services can be split into the contribution of hours worked and the contribution of changes in labour compensation or into different contributions by skill level (or age or gender).

In the following sections, an appraisal of the UK construction industry is undertaken in terms of resource usage and productivity, utilising the basic variables, growth variables and additional series from the database by consideration of value added volume, trends in labour productivity, changes in input usage based on factor shares and the categorisation breakdown of those factor shares and finally TFP.

In this appraisal, the choice of areas for analysis is based on an attempt to highlight some of the particularly useful aspects of the available data. For instance, a focus of the component breakdowns of inputs concerns the complementary patterns of change in the use of skilled labour and ICT capital. Throughout these sections the analysis is based on data derived from the EU KLEMS Productivity and Growth Accounts.

4.1 Growth rate of value added volume

It is well-documented (by Barras (2009) and many others), that the construction industry is subject to higher rates of fluctuation in its level of activity than other sectors of the economy. Figure 1 allows a comparison between value added change in construction and total industries (i.e. the aggregate of the forty sectors). In comparison with other industries, the construction industry rate of change in value added is much more exaggerated in periods of economic boom or recession than other industries.

During the boom period of the late-1980s, for instance, the growth rate for construction peaked at 11.2% in 1987 but the total industries rate only reached 5.1% in 1988 and, during the 1991 downturn, the construction industry's 8.3% negative growth rate far exceeded the total industries decline to -0.5%.

Figure 1. Growth rate of value added volume (% per year): UK construction industry and total industries

Even more extreme, has been the comparative effect on the contribution of hours worked to value added growth, with workers laid off or put on shorter working hours much more readily in the construction industry compared to other sectors. For instance, for the construction industry, the decline from the peak growth rate of 6.9% to the low of -11.9% over the period 1988 to 1992 compares to a change from 3.5% to -3.2% for total industries over the same period, as shown in Figure 2. Conversely, the comparative increase in growth was at a far higher rate for construction during upturns in the economic cycle.

Figure 2. Contribution of hours worked to value added growth (% per year): UK construction industry and total industries

4.2 Trends in labour productivity

General trends in labour productivity: Value added per hour worked

Cross-industry comparisons can be made in terms of the value-added per hour worked as a measure of productivity. There are significant differences between the rate at which value added per hour worked in different sectors of the economy has changed in recent decades. In Figure 3, the construction industry is compared to total industries, manufacturing and post and telecommunications - the latter being an example of an industry that has most benefited from new ICT development. In the construction industry, value added per hour worked in real terms shows a consistent, moderately rising trend since 1977. Throughout the period, gross value added per hour worked in the UK construction industry has remained at about the same level as that of total industries whereas, since the late 1980s, for manufacturing it has grown significantly and for post and telecommunications (ISIC 64), a high technology industry, increased exponentially.

Figure 3. Value added per hour worked in selected UK industries (1977 = 100): An inter-industry comparison

Making international comparisons for the construction industry (Figure 4), the aggregate EU-15 countries also show a similar rising trend to the UK (albeit at a lower level), even though there are significant differences between the constituent countries. In the USA, however, the construction industry has been one of the poorest performing sectors, with a steadily declining level of value-added productivity – one of the few sectors in that country to do so. In Japan, the upward trend of the 1980s was replaced in the 1990s by a steady decline and a levelling off post-2000. With Japan having experienced a prolonged period of economic stagnation since the beginning of the 1990s, the construction industry began to experience declining values since 1990 and, by 2007, the index was back to its 1987 levels.

Generally, labour productivity in construction is particularly low. There is a wide range of levels in growth across industry sectors, which suggests that industries differ significantly in their production technologies. Whereas Kuznets (1971) and Maddison (1980) noted the slow growth of labour productivity in services and construction compared to manufacturing industry from the late 1940s until the 1960/1970s, since the 1980s, the ability to utilise and take advantage of information and construction technology has been a major factor in determining an industry's ability to raise its labour productivity at a higher rate.

Figure 4. Value-added per hour worked in the construction industry (1977 = 100): An international comparison

4.3 Changes in input usage

The long time series in the EU KLEMS factor database permits a longitudinal study of resource usage over the period. In terms of inputs, in addition to consideration of the changing capital : labour ratio over time, the breakdown of factor compensation data allows comparative usage of different categories of labour and of capital to be measured.

For example, in terms of labour, the breakdown of compensation data by skills levels allows comparisons to be based on the skills mix and questions to be considered, such as: Has the construction industry become more skills intensive over time and what happens to the skills mix during periods of recession in the industry?

Regarding capital usage in the industry, a widely accepted view is that the industry has fared poorly in its ability to take advantage of developing ICT. Data on the split of capital usage into between ICT and non-ICT capital enables consideration of the validity of the view that construction is an industry with an inability to take advantage of developments in ICT compared to most manufacturing and service sectors.

4.4 Factor shares and the use of ICT and skilled labour

Dynamic change in any industry entails not only changes in output and productivity but also shifts in the mix of inputs. As Jorgenson and Timmer (2009) point out, generally technical change favours inputs that are well-suited to the generation and processing of knowledge and information i.e. skilled labour and ICT capital.

In order to track, over time, the use of labour and capital inputs in an industry, cost share (price times quantity) data can be used. The relative share of the two inputs (or input intensity) is determined as:

$$P_L Q_L / P_V Q_V \text{ and } P_K Q_K / P_V Q_V$$

Where $P_V Q_V$ is the total value added with a cost share of $(P_L Q_L)$ for labour and $(P_K Q_K)$ for capital respectively.

4.4.1 The labour-capital compensation mix

The share of labour compensation in total value added for the construction industry has generally been at around the 70-75% mark throughout the period. This is consistent with Kaldor's (1961) view that there is a 'natural' level for the split in value added between labour and capital. As can be seen in Figure 5, this has been similar to the total industries level apart from the 1990s, when labour compensation in the construction industry averaged around five percentage points higher. For comparison purposes, it can be seen that the business services sector saw a relative shift away from labour compensation, as ICT investment took off in the 1990s.

Figure 5. Share of labour compensation in value-added: A UK inter-industry comparison

4.4.2 Trends in labour compensation

Labour compensation is determined by the two elements of labour services per hour worked and the number of hours worked. What has been a significant trend has been the trade-off between these two components over time. There has been a very notable trade-off between the cost of labour services per hour worked and the average number of hours worked and there is a strong inverse correlation between the two variables. As

wage costs have increased, the average number of hours worked per worker has tended to fall.

Figure 6 illustrates that the rise in the hourly cost of labour services has been accompanied by a declining trend in the average number of hours worked over the period, with the recessionary years of the late 1980s to the early 1990s being the exception due to a decline in average wages.

Figure 6. Labour services per hour worked and average number of hours worked in the UK construction industry

4.4.3 Changes in the skills mix

A breakdown of the labour input categorised into three skill levels enables changes in the use of skilled labour to be tracked. The definitions of high, medium and low skills are consistent over time for each country but do differ across countries. For the UK, High-skilled refers to university degree or equivalent; Medium-skilled includes qualifications from trade apprenticeship, GCSE, BTEC/HND or equivalent; Low-skilled means no qualifications (Timmer et al, 2007b). Incorporating educational attainment as a measure of skill may be too restrictive for comparisons across countries, but is useful for tracking developments over time within a particular country such as the UK.

In terms of the compensation share of workers categorised by skill, there are large differences between industries in the use of high-skilled labour. In the UK, as in other countries, construction is invariably among the least skill-intensive industries. This is remarkably consistent over time. A feature of the EU KLEMS database is that each of

the inputs is defined as a translog function of its components. The weighting procedure means that, for instance, a doubling of hours worked by a high-skilled worker gets a bigger weight than a doubling of hours by a low-skilled worker.

An interesting aspect of the trend of the skills mix is the variation in the volume growth rate of labour use by skill category. In Figure 7, it is apparent that there is a high degree of correlation between the growth rate for high-skilled and low-skilled labour but the pattern for the use of medium-skilled labour is much more extreme in terms of the level of change during upturns and downturns. This indicates that the use of technical staff and craft level workers is subject to the greatest changes during periods of downturn and upturn in construction activity.

Figure 7. Skills compensation breakdown in the UK construction industry - Annual average volume growth rates (%)

4.4.4 Trends in capital compensation

ICT capital intensity is difficult to measure because the quantities and prices of capital services are not directly observable. Based on the capital services approach (Jorgenson and Griliches, 1967), the capital input can be measured through its delivery of services as measured by user cost. This approach takes account of the fact that the annual amount (value) of capital services delivered per £ investment in ICT is much higher than, for instance, than that for buildings.

In the EU KLEMS database, ICT assets include IT assets, communication technology assets and software. ICT intensity is measured by total capital compensation multiplied by the share of ICT assets in total capital compensation divided by the nominal value-added. As pointed out by Ruddock (2006), the benefits from investment in ICT in the construction industry in terms of improved efficiency and productivity are notoriously difficult to determine accurately. Figure 8 shows that ICT capital services growth rates have been much less volatile than non-ICT. ICT intensity of production has doubled or

even tripled over the period from 1980 to 2005. This rapid increase in the share of ICT in value added (from an obviously low base) can be attributed to strong substitution with ICT induced by the rapid decline in its price relative to non-ICT assets and labour.

Figure 8. Capital services breakdown in the UK construction industry - Annual average volume growth rates (%)

4.5 TFP growth trend

When the growth in value added is decomposed and the contributions of factor inputs are removed, the residual is TFP growth. TFP includes a range of effects and its value can be affected by many factors. Ruddock and Ruddock (2009), for instance, indicate that issues such as the effects of organisational change and the non-inclusion of intangible capital investment can significantly affect the value of TFP.

In effect, value added TFP only provides an indication of the importance of productivity differences in factor inputs. Figure 9 shows the TFP contribution to value added growth for the UK, USA and Germany (for the various periods for which these data are provided in each country's accounts). In each case, there have been periods in which the annual growth of TFP has been negative but for the UK the average annual growth rate over the period 1981-2007 was 0.68%. This compared favourably with the negative TFP growth rates of -0.78% (1992-2007) for Germany and -2.15% (1978-2007) for the USA. The figures corroborate the results of the study by O'Mahoney and de Boer (2002), in which, for the period 1989-99, they estimated the annual TFP growth rate to be 0.69% for the UK but negative for Germany and the USA.

Figure 9. Contribution of TFP to value added growth (%): International comparison

5 CONCLUSION

With a database covering almost four decades, the EU KLEMS Growth and Productivity Accounts provide a rich source of information for the analysis of productivity growth in the construction industry. The use of detailed data on, and measurement of, the sources of growth at the industry level and the breakdown of labour into categories and capital inputs into asset types is an essential step towards better assessment and understanding of productivity changes. The broad results from the analysis undertaken, indicate that there is some evidence that the sources of growth in the construction industry are different from other industries.

In terms of the basic factors of labour and capital, labour is the most important input in terms of cost share. With the labour inputs, the growth attributable to labour compensation has tended to show only a limited degree of change over the period except during recessionary periods (such as the early 1980s and 1990s) and, if the construction industry is compared to many other industries, the relative level of labour compensation is low. Even though much construction work is considered to be labour intensive compared to other industries, the comparatively low skill level of the industry's workforce is reflected in a lower level of remuneration.

The fastest growing category of input is ICT capital although its share in overall costs is still modest. Also, for the capital variables, the extent to which growth is attributable to change in non-ICT investment is much more affected by change in the economic cycle than it is in the far steadier pattern depicted by the level of investment in ICT.

There is strong correlation between the use of skilled labour and ICT at the industry level. Simultaneous increases in the use of skilled labour and ICT indicates capital–skills complementarity and, therefore, indicates a need for an investigation of links between these drivers of technical change. The need is not new but the evidence presented emphasises its importance.

TFP growth appears to be small (sometimes even negative on an annual basis) indicating that the overall technical efficiency with which the labour input has been used is not increasing. A negative value for TFP growth means (in theory) technological regression but, in practice, could include measurement errors and other factors such as the omission of intangible investment in capital usage (O'Mahoney and Turner, 2009). Soft innovations, such as organisational change, and other intangible investments are much more difficult to measure than hard technologies. At the sector level, Basu et al (2003) focused on how far TFP growth can be explained by investment in organisational capital, which they argue is necessary to reap the benefits from a general purpose technology such as ICT. They use the growth in ICT investment as a proxy for organisational capital and find a suggestion of an initial fall in TFP, in the UK before the benefits are realised in the longer run. The level of investment in ICT might be expected to determine the level of growth in productivity but a time lag is inevitable for the implementation of new technology to realise its full potential. Processes to make products are re-engineered together with restructuring the business before real gains are achieved.

The evaluation of productivity in the construction industry can be fraught with difficulty but this analysis has considered how the availability of detailed industry data, particularly on the use of labour and capital, can potentially be an extremely useful tool in the development of more valid assessments.

Abstract:

This paper presents the current big issues in cost management. It covers the theoretical aspects, the causes and effects, and possible countermeasures. This paper is a result of a literature review conducted during the initial stages of a doctoral research. In doing so, principles of lean production are considered as a basis for critical evaluation. Seven big issues have been identified as shortcomings in the current construction cost management approaches. Some of such issues identified are failure to forecast, failure to pinpoint improvement opportunities and poor support to inter-organizational cost management. Possible countermeasures are suggested to address the identified issues. This research is expected to contribute towards developing conceptual solutions for improving the cost management approaches.

Keywords:

cost management, lean, value, waste.

1 Introduction

Cost management can be generally considered as a set of techniques and methods for controlling and improving a company's activities and processes, its products and services, to achieve cost effectiveness (cost reduction, value improvement and substitution) by collecting, analyzing, evaluating and reporting cost information for budgeting, estimating, forecasting and monitoring costs, in order to assist decision making.

Since the seminal contribution by Kaplan and Johnson (1987), literature indicates extensive discussions highlighting the need for improvements in cost management. Through a review of such literature, this paper aims to establish and consolidate the big issues in construction cost management, especially when analyzed from lean production perspectives.

Following this introduction, each big issue is discussed in terms of introducing the issue, the causes, an explanation, and possible countermeasures. A discussion identifying areas of commonality, consequences of the weaknesses, and areas for improvement are identified. Finally, conclusions and further research directions are indicated.

2 BIG ISSUES IN TRADITIONAL COST MANAGEMENT

2.1 Failure to Forecast

Forecasting is one of the key functions of cost estimation in construction projects. Zwikael and Smyrk (2009) have defined “project” as a form of investment in which outlays (approved by “funder”) are made today with the intention of realising a flow of benefits over some future timeframe. Cost estimation is used to establish the probable cost of a future project or product, before designed in detail and contract particulars being prepared. In this way, the client is made aware of the likely financial commitments before extensive design work is undertaken (Seeley, 1983) and it can help in providing correct input to him for making the correct decisions on future investments. Forecasting has been discussed as part of attempts to improve accuracy in estimating (Jaya et al., 2010, Rosenfeld, 2009, Beeston, 1986, Ballard, 2008, Kenley and Wilson, 1986). However, Flyvbjerg (2008) and Elfving et al. (2005) believe that these endeavours have not been fruitful.

Many causes of inaccuracy have been pinpointed in previous research. Traditionally, it is common for building owners to decide on relatively detailed issues at the beginning of the project delivery process for the preparation of tender documents. There is a high possibility that the detail issues in the design at this early stage will change along the project delivery process, hence causing a considerable amount of waste in terms of time, information provided, and waste created during construction due to design faults (Elfving et al., 2005). In addition, cost is just understood to be there and the focus is on targeting for the ‘expected cost’ and not for ‘targeted cost’. Flyvbjerg (2008), introducing the term “dark side of forecasting”, points out unethical practices such as project champions / person in-charge (planner & the politicians) proceeding with projects even when inaccuracy in estimating is detected at the outset.

Currently, most of the cost data are taken from previous projects, which inherit waste. Such waste can be in varying amounts due to the emerging nature of waste. This fact is not acknowledged when compiling and using cost data, thereby resulting in inaccuracies in cost estimates.

Therefore, a possible countermeasure is to develop cost management approaches which account for the emergent nature of waste in the total construction process.

2.2 Failure to Pinpoint Improvement Opportunities

Current practices have witnessed many estimators being more keen on getting projects to be funded and built (Flyvbjerg, 2008) rather than getting the forecast right. In addition, early commitments to design solutions have established cost at the initial stage. Locking the cost and the design, reduces the opportunity to decrease the cost during construction, even though many authors have agreed that 70%-80% of product costs are committed during the concept phase (Rush and Roy, 2000). It is also highlighted that making a wrong decision at this stage is extremely costly further down the development process where product modifications and process alterations are more expensive. This situation may significantly increase resource consumption and generate waste (i.e., waiting and rework) (Elfving et al., 2005, Koskenvesa et al., 2010) and also reduce the product flexibility.

Causes of this issue include referring to cost data from sources such as Spon's Construction Price Book and BCIS (Building Cost Information Service), where information taken from previous projects include inherent waste. The usage of such data seems to slow down the growth of the labor productivity (Koskenvesa et al., 2010). In addition, Elfving et al. (2005) reported that decisions on early detailed issues in design might increase the probability of changes later on, which often leads to suboptimal solutions, quality defects and rework and this indirectly will contribute wastes in the process. In addition, initiatives in cost reduction have focused more on direct labor time instead of overhead cost where costs are actually increasing most rapidly (Kaplan and Johnson, 1987).

Koskela and Tommelein (2009) argued that cost can also be influenced along the entire project delivery. Target Value Design techniques (Kim and Ballard, 2000, Ballard and Reiser, 2004), which can influence the cost along the project delivery process, is one solution that can be adopted.

2.3 Costs are Shaped by Action rather than Result from Action

Kirkham (2007) points out that traditional cost planning will usually follow the conventional process structure of outline design, detailed design. This cost plan (estimate) is the basis of cost control.

Conventionally, cost control techniques are used during the design stage to enable the architect to be kept fully informed of the cost implications of all his design decisions, and throughout the construction period in order to rectify mistakes resulting by the action of the parties at the early stage of the project (Seeley, 1983). This situation, which set strategies based on the client's requirements, earlier on before the project started is referred to as the 'cost result from action' thinking and arguably leads to increased inaccuracy, creation of waste and also failure to achieve cost reduction.

Cost can be influenced in a positive way by the actors throughout the project delivery process. Therefore, it can be established that costs are 'shaped by action', and it is possible to make the design converge to an acceptable overall project cost rather than letting the cost reflect the design.

Adopting target value design (Ballard, 2010), which drives design to deliver customer values and develops design within project constraints, can influence cost along the project delivery process, in contrast to only predicting costs at the beginning of the project.

2.4 Relative Neglect of Value Consideration

When browsing through the index in books (Brook, 2008, Hillebrandt, 2000, Seeley, 1983), which are related to cost management, a missing discussion in value aspect can be witnessed. Traditionally, value has not been addressed in construction cost management, although many feel that the important criterion of value should be taken into consideration. The only problem is that they do not know where and how to do it.

Value consideration is necessary for construction project for allowing to achieve the best value for money by eliminating unnecessary costs and functions while maintaining and optimising the performance. Studies in value have addressed the provision of 'value' but ignored the concept of value from the customer's perspective (McNair et al.,

2001). Activity-based management approaches (Kaplan and Cooper, 1998) are used to divide the activities and costs of the firm into value-added or non-value-added categories, but it remains unclear whether and how customers' perspective is embedded into these approaches (McNair et al., 2001). The use of target costing (Tanaka et al., 1993) is considered of very limited value (Ewert and Ernst, 1999) to the overall cost management even though it relates cost to product attributes and its primary aim remains in cost minimization and value as proxy by market price is used only to define allowable costs (McNair et al., 2001).

All these techniques do not enable an identification of which activities should be emphasized and provide no assessment of specific linkages between internal cost structure and externally defined value (McNair et al., 2001). In summary, looking at the issues mentioned above, each tool mentioned fails to fully explain the complex relationship between cost and value (McNair et al., 2001).

It is suggested that the continuous monitoring of loss of value is needed by creating a better alignment between cost and value for helping the firm target areas where costs can best be leveraged to improve its overall profit potential (McNair et al., 2001). It started from the design stage until the construction stage for the success of value towards client's requirement. Continuous monitoring of loss of value is needed because cost management system is not aligned with the development in production process and value is not considered in it. Benefit realization management (Yates et al., 2009) and Choosing by Advantages (Suhr, 1999) are other alternative approaches to get the optimum result of project/product.

2.5 Poor Support for Inter-Organizational Cost Management

Currently, many-tiered supplier networks exist in traditional supply chains (Cooper and Slagmulder, 2004), where the connection between key supplier's suppliers, key supplier's other customers, customer's other suppliers' and customer's customer (Dubois, 2003) exist. These many-tiered supplier networks create a major addition in transaction cost until it reach the final customer, and it is believed that customer carries mostly the burden of cost accumulation in traditional supply chains (Kulmala et al., 2002).

The costs of purchased goods and services represent the majority of total costs for most companies (Dubois, 2003). Therefore, outsourcing purchased goods mostly happen chasing the lowest price for each transaction. All of these goods and services are purchased from supplier organizations and the purchases from supplier organizations are the largest single expenditure for most firms. This high share is attributable to the ambition of companies to concentrate more on their specialisation (Dubois, 2003). Furthermore, as time goes by, outsourcing of manufacturing activities has been followed by outsourcing of design and development work and therefore, suppliers are contributing to the technical development of a company (Dubois, 2003). Moreover, applying new techniques such as JIT (Just-In Time) and TQM (Total Quality Management) require active involvement of suppliers and affects the costs and benefits of both buyer and supplier (Dubois, 2003).

The cost management problems caused by the many-tiered supplier networks can be alleviated by adopting relational oriented philosophies (Kulmala et al., 2002, Kulmala, 2004), applying open book accounting (Kulmala et al., 2002, Seal et al., 1999) and

redefining of the unit of analysis (Dubois, 2003, Cooper and Yoshikawa, 1994, Christopher and Gattorna, 2005, Cooper and Slagmulder, 2004, Zimina and Pasquire, 2010, Cabral and Riordan, 1989).

2.6 Negative Influence on Behaviour

Several forms of negative influence from cost management systems on behaviour have been identified in literature, ranging from claim culture to manipulation of bids and performance measurements. Attitudes that relate to the occurrence of claims in the administration of contracts show that the industry has a culture that is opportunistic, prone to conflict and resistant to change (Rooke et al., 2003). People draw on whatever resources they can to make the best out of a bad job in order to get by and get things done to make extra profit or money (Rooke et al., 2003). There are contractors who expend more effort on generating profit from claims than from improved construction methods (Rooke et al., 2004).

Another example is 'unbalanced bid', which has the tendency to create cash constraints to many parties, such as cash flow problems to contractor (Tucker, 1986, Ali and Elazouni, 2009, Qingbin et al., 2010, Chen et al., 2008, Elazouni, 2009), financial disorder to client (Christodoulou, 2008) and also to both parties, when managing more than one project (Lu et al., 2007). This whole example will create a false alarm. In addition, the earned-value method, which is developed for integrating schedule and cost management, creates the opportunity to project managers to manipulate work sequences when releasing work to the field. In this situation, it may be work assignment that are not shielded from uncertainty are release for the sake of early payment (Kim and Ballard, 2000).

The blame is not only on contractors' part but can also happen because of client behaviour. Consistently, late payments by clients have encouraged contractors to act negatively because of the resultant cash constraints problems that they have to face.

Some countermeasures were suggested by Arditi and Chotibhongs (2009), Christodoulou (2008) and Cattell et al. (2008), where models were suggested to overcome the problem of unbalanced bid. Adoption of procurement methods that discourage claims, and open book accounting (Kulmala et al., 2002, Seal et al., 1999) are another possible solutions available.

2.7 Budgeting in Dynamic Situations

The budgeting emerged in the 1920s as a tool for managing costs and cash flow in large industrial organizations such as DuPont, General Motors and Siemens. Budgets are also used extensively in construction contexts too. Currently, a number of companies have recognized the full extent of the damage done by budgeting (Hope and Fraser, 2003b). They have rejected the reliance on obsolete data and the protracted, self-interested wrangling over what the data indicate about the future because it render pointless interpretation and circulation of current market information, the stock-in-trade of the knowledge-based and networked company.

Having a budget in a business unit, have created negative scenarios among employees in an organization because each and every activity involved in the product delivery process will be benchmarked with a budget. This will disempowers the front line, discourages information sharing, and slow the response to market developments until it's too late

(Hope and Fraser, 2003a). The usage of budget, which is at first to force performance improvements, have lead to a breakdown in corporate ethics where information is only funnel to those with a “need to know” and not the rest of the team (Hope and Fraser, 2003b).

In the absence of a budget, alternative goals and measures are move to foreground and business units and personnel performance is judged on how well its performance compares with its peers’ and against world-class benchmarks that is collected and prepared by specialist firms that understand the particular industry. The result of this adoption has created more accurate interpretation of results (Hope and Fraser, 2003b).

Traditionally, early creation of a budget has been emphasized in construction project management. However, the dynamic situations in construction projects may demand a more flexible and a responsive approach to budgeting. A possible countermeasure is to develop cost management approaches which take the above in to consideration.

3 Discussion

When analysing the big issues, some common causes can be identified. They can be divided to four subsections, i.e. assumptions on how cost emerge, assumptions on management need for cost information, assumptions on conditions or context in cost management and how contract is formulated and payments arranged (Table 3).

Table 3: Common causes in the seven big issues

COMMON CAUSES	OUTLINE OF COMMON CAUSES	BIG ISSUES FEATURED
Assumptions on how cost emerge	Key underlying assumption is: Costs do not cover any avoidable waste	Costs are shaped by action rather than result from action Failure to forecast Negative influence on behaviour Poor support for inter-organizational cost management Failure to pinpoint improvement opportunities
Assumptions on management need for cost information	Key underlying assumption is: Cost information is only needed for decision-making	Poor support for inter-organizational cost management Failure to forecast
Assumptions on conditions or context of cost management	Key underlying assumptions are: Design and production occur in a static environment. The same value will be achieved through alternative course of action.	Relative neglect of value consideration Budgeting in dynamic situations Costs are shaped by action rather than result from action
How contract is formulated and payments arranged	Contract or payment arrangement creates an incentive for one party to manipulate design and production to its own advantage.	Negative Influence on behaviour Costs are shaped by action rather than result from action Failure to forecast

The consequences of the big issues in cost management do include inaccurate price of a project/product, suboptimal solutions, quality defects and rework, reduced growth of labour productivity (Koskenvesa et al., 2010), reduced product flexibility, increased resource consumption, making wrong decisions, cost accumulation to the customer, cash flow problems and bad financial planning.

These big issues have exposed significant weaknesses in the traditional cost management approaches. Based on the literature review findings, it seems that many parties have realised these problems that have existed in the current cost management system. Yet, hardly any of the initiatives that have been put forward seems sufficient as such for achieving a needed overhaul of the function, role and philosophies of the cost management system. Transparency of the cost and the thinking out of the box are required in order to improve. In addition, structural changes such as improvement in training and education towards the purported changes and revision of the procurement policies are suggested as well.

4 Conclusions

Effective cost management is important for the achievement of the investment put forward by the sponsor of the project. Therefore, in order to provide accurate guidance to the decision maker in initiating and making their decision, consideration of value,

achievement of maximal accuracy and reduction in cost are very important to be achieved in every cost estimation exercise. This paper sees that the real problem to the success of cost management is to find ways to reduce the amount of wastes that are embedded in the current construction costs. Informed by this review, the future direction of this research is to develop conceptual solutions to the current problems in construction cost management identified here.

Education and training

Revisiting the Logistics Course Content of Tertiary Construction Management Education in South Africa

F.A. Emuze, J.J. Smallwood and W.M. Shakantu

Department of Construction Management,
Nelson Mandela Metropolitan University, PO Box 77000,
Port Elizabeth, South Africa, 6031

Abstract:

The management of the physical construction process is significantly characterised by conversion processes, which requires competencies in logistics management. However, the management of construction logistics in South African construction is reportedly sub optimal, though it could benefit substantially from logistics management tools. Recognising the usefulness of these tools, and motivating for their deployment in South African construction therefore requires site managers / agents that are competent. In this context, competence is relative to logistics. Therefore, as part of a longitudinal research project, this paper reports on a pilot study conducted among BSc (Honours) (Construction Management) students registered at a South African university. Selected findings include: students perceive that the academic programme has not adequately prepared them for logistics related site management roles in the industry. Specifically, they say the programme failed to significantly increase their knowledge, skills, and understanding relative to logistics management tools such as reverse logistics. Clearly, there is a need to revisit the programme and address issues raised by the respondents so that future construction management graduates can be confident in their ability to management construction site related internal and external logistics upon graduation from the university, thereby enhancing the management of logistics in South African construction.

Keywords:

construction management, education, knowledge, logistics, South Africa

1 Background

The council of logistics management (CLM) defines logistics as that aspect of the supply chain process that plans, implements, and controls the efficient, effective forward and reverse flow and storage of goods, services, and related information between the point of origin and the point of consumption in order to meet customers' requirements (Blanchard, 2004). In other words, logistics management refers to the science of planning, procurement, maintenance, distribution and replacement of materials and personnel. This means having the right person / vehicle / equipment / material in the right place at the right time. In terms of construction projects therefore, principal responsibilities of a construction / project manager revolves around the optimisation of daily operations through careful planning, organising, directing, and controlling activities before and during construction. Therefore, operational efficiencies that involve day-to-day decisions relative to logistics are directly part of the responsibilities of site management.

In this context, construction logistics activities include: material supply, storage, processing and handling; manpower supply; schedule control; site infrastructure and equipment location; site material flow management on a job site, and management of information related to all physical and services flows (Jang *et al.*, 2003). As an illustration, in order to perform an activity or carry out a task on site, certain conditions must be fulfilled. These conditions entail the availability of appropriately skilled labour, materials, access to work area, plant and equipment, design information, completion of previous critical tasks, acceptable weather conditions, and agreed safe work procedures. Should one or two of these conditions not be met or available, a task cannot be completed and the construction process is delayed.

In spite of this knowledge, the situation in the South African construction industry relative to logistics and its management is considered sub-optimal. Specifically, based upon multi-case study research conducted in Cape Town a major South African city, Shakantu *et al.* (2008) pointed out that the logistics of building materials and construction and demolition (C&D) waste are not integrated, and that the movements for both materials delivery and C&D waste are inadequate. They affirmed that integration of disparate logistics would not only provide scope for utilisation of spare capacity, but would also ultimately improve the logistics of the construction industry as the utilisation of spare capacity would immediately increase the utility of vehicles, reduce unit costs, and also lower the number of empty vehicular movement in and about construction sites. Similarly, in Brazil, Nunes *et al.* (2009) observed that there is a need to introduce the concepts of reverse logistics so that municipal managers can improve the reuse of C&D waste, and recycle them by compiling a reverse C&D waste network that can optimise flows and activities.

Therefore, the research reported upon in this paper addresses the educational gaps that may be contributing to logistics related problems in South African construction. The optimisation of construction logistics management or rather the management of construction logistics is thus examined through the lens of construction management students that are expected to fulfil logistics related roles upon their graduation from the university. The study was undertaken in order to assess the readiness and / or ability of the students to improve the management of construction logistics in South African construction. Perhaps addressing the issue at the early stage of construction management education may have desired effects on how logistics related functions / activities are carried out in the industry.

2 Literature Review

Venkataraman and Pinto (2008) contend that project operations function creates value by converting raw materials and components into a finished product at every phase of the supply chain; it is responsible for ensuring quality, and reducing waste, and shorter process lead times. In fact, informed research findings indicate that active involvement in the management of construction logistics not only result in improved main contractor / subcontractor interface, but also enhance the subcontractor / subcontractor interface (Perera *et al.*, 2009). The importance of managing construction logistics is in fact underscored by the 2003 report of the Building Research Establishment (BRE) that discovered that almost 30% of construction cost could be attributed to the transportation and / or movement of construction materials (BRE, 2003 cited by Shakantu, 2009).

The 2003 findings by the BRE should not be mindboggling as Udeaja and Tah (2005) contend that the characteristics of construction material supply chains include:

- Multiple organisations are often involved in the supply chain;
- Organisations are physically distributed, which may be across one site, across a country or even continents;
- In a project or inside organisations, there is a decentralised ownership of the tasks, information and resources involved in the supply chain;
- Different groups within the project or inside organisations are relatively autonomous. They control who, at what cost and in what time frame, consumes resources. They also have their own information systems, with their own idiosyncratic representations, for managing their resources;
- There is a high degree of natural concurrency. That is, many interrelated tasks are running at any given point of the supply chain process;
- There is a requirement to monitor and manage the project. Although the control and resources of the constituent sub-parts are decentralised, there is often a need to place constraints on the entire process, and
- Material supply chains are highly dynamic and unpredictable. It is difficult to provide a complete priority specification of all the activities that need to be performed and how they should be ordered. Any detailed time plans which are produced are often disrupted by unavoidable delays or unanticipated events.

The delivery of materials on most projects may therefore be delayed due to the inability to create transparency in terms of movement / transportation either on site / or elsewhere along the supply chain on the one hand; and the uncertainties that surround material availability for project tasks without unnecessary stockpiling on site on the other hand (Ala-Risku and Karkkainen, 2006). Thus, logistics management that focuses on material movement is intended to introduce efficiency in the construction process because project management is principally concerned with the effectiveness of the construction process, while logistics management is an approach concerned with optimising flows within an organisation (Fisher and Morledge, 2002). In general, construction logistics functions can be divided into supply logistics and site logistics. Supply logistics are related to activities in the production process that are cyclic in nature. These activities include the specification of supply resources such as materials, equipment, and labour, supply planning, acquisition of resources, transport to a site and delivery, and storage control. Site logistics are related to the physical flow of on-site processes such as the management of handling systems, safety equipment, site layout, defining activity sequence, and resolving conflicts among various production teams related to the on-site activities (Jang *et al.*, 2003).

The diverse variety of cultural relationships, which has created what is often described as adversarial and fragmented industry, can be said to have fostered a fragmented and inefficient approach to logistics management in the industry (Sullivan *et al.*, 2010). In fact the importance of construction logistics to project managers in the industry is exemplified in a number of empirical research findings. For instance, the work of Jang *et al.* (2003) demonstrates this importance, when they report that key construction material logistics factors such as personnel, material flow, schedule adherence, contractors' organisation, and information flow have significant relationships between

the construction logistics process and satisfaction of project managers. This indicates that the factors are significant predictors of overall satisfaction for the construction logistic process.

It follows that the realisation of efficiency gains in construction is dependent on reliable information flow and logistics related activities including the forward and reverse flows. Furthermore, clients' demand for project performance improvement necessitates the adoption of sound logistics management practices in the industry. For example, building information modelling (BIM) and information technology (IT) collaboration tools have set the stage for substantial change and by implication improvement in the design and construction process. BIM and IT collaboration technologies potentially facilitates standardisation / or modularisation in off-site locations that offers greatest production efficiency and quality.

In addition, with the use of IT tools such as vendor-managed-inventory (VMI) in construction, the time and work relative to logistics and administration functions to manage procurement of small items on construction sites can be reduced significantly (Tanskenen *et al.*, 2009). Also, Song *et al.* (2007) report that the location of materials in motion as well as those in the stockyard can be tracked through the use of material tracker integrated with radio frequency identification (RFID) and Zigbee. Tracking-based method for solving the difficulties related to site inventory management and transparency can thus be considered a useful way forward because of its reported practical relevance in the construction industry context (Ala-Risku and Karkkainen, 2006).

To be succinct, the construction management literature suggests that efficiency gains accrue if the concept of logistics management is optimised in construction as logistics adds value to economic activities in the construction process through place and time utility (Coyle *et al.*, 2003). Logistics provides place utility by moving goods from production surplus points to where demand exists and time utility by making sure the goods are available when they are needed. It therefore creates place utility primarily through transportation, and time utility through proper inventory maintenance and strategic location of goods and services.

3 Research Methodology

The research method adopted for data collection was quantitative in nature as all 2010 BSc (Hon) (Construction Management) registered students at the South African university are full time students who undertake lectures and / or reside in more than one campus of the institution. Hence, the structured questionnaire was hand delivered to the students and also distributed to them through their university e-mail addresses. At the end of the time allotted for the survey, all the registered students returned their validly completed questionnaire. In other words, 12 valid responses were received out of a total number of 12 registered students surveyed, which equates to a 100% response rate.

The questionnaire elicited for information related to the extent that the construction management undergraduate (BSc) and honours (BSc Hon) academic programme have contributed to an increase in knowledge in certain logistics related areas, and the understanding of the functions of site management functions relative to logistics with two (2) questions and eight (8) sub-questions. The questionnaire also sought perceptions

of the students in terms of how the academic programme has enhanced site management skills with nine (9) sub-questions that underpinned a question. In general, given the exploratory nature of the study, three (3) questions, and seventeen (17) sub-questions that were structured; and one (1) unstructured question constituted the basis of the findings.

Though the structured questionnaire was based on the literature reviewed and informal discussions with undergraduate students, it nevertheless provided opportunity for the students to express their views pertaining to their ability to confidently undertake logistics related responsibilities upon their graduation from the university. In particular, the last question in the questionnaire that requested for general comments from students provided the opportunity to express other views not captured in the structured instrument.

The quantitative method was used for data collection not because it is reportedly the dominate method in Construction Management Research (CMR) (Dainty, 2008), but primarily because of the need to provide an objective basis for in-dept future investigations that are intended to be driven by the dominant views of the respondents (construction management students). This position is supported by the positivism view, which states that all phenomena should be understood through the employment of a scientific method so as to create a theoretically neutral language of observation that remove subjective content from assumptions (hypotheses and theories) with the overall intent of arriving at deterministic findings that de-emphasise free will, emotion, chance, choice and morality (Collins, 2010).

4 Findings

The interpretations and discussions of the research findings are based on Mean scores (MSs) comparisons relative to percentage responses to five point likert scale questions in the form of MS ranges as indicated in Table 1. The ranges in Table 1 are computed based on the five-point likert-scale type questions as the difference between the upper and lower ends of the scale is 4.00 and there are five points, each range can be equated to 0.80 since the extent of the range is determined by a division between 4.00 and 5.

Table 1. Terms used to discuss mean score comparison

Mean score range	Meaning
$> 4.20 \leq 5.00$	Near major extent to major extent / major extent
$> 3.40 \leq 4.20$	Some extent to near major extent / near major extent
$> 2.60 \leq 3.40$	Near minor extent to some extent / some extent
$> 1.80 \leq 2.60$	Minor to near minor extent / near minor extent
$\geq 1.00 \leq 1.80$	Minor to a near minor extent

Table 2 indicates the respondents' perceptions of the extent that BSc construction management undergraduate and BSc (Honours) academic programmes have contributed to an increase in logistics related knowledge areas in terms of percentage responses to a scale of 1 (minor) to 5 (major), and a MS ranging between 1.00 and 5.00. It is notable that out of the listed knowledge areas, only two achieved MSs above the midpoint score of 3.00, which indicates that the respondents are of the opinion that the contribution of the construction management academic programmes to these two knowledge areas are more of a major than a minor extent.

Though, there was no MS above 3.40, the MSs $> 2.60 \leq 3.40$ indicate that the respondents perceive that the construction management academic programmes' contribution to increased knowledge in material handling and inventory related issues can be deemed to be between some extent to a near major extent / a near major extent. While the MSs $> 1.80 \leq 2.60$ suggest that the contribution can be deemed to be between minor to a near minor extent / a near minor extent.

Table 2. Extent to which the academic programmes contribute to an increase in logistics related knowledge areas

Logistics knowledge area	Response (%)						MS	Rank
	U	Minor.....Major						
		1	2	3	4	5		
Material handling	0.0	7.7	15.4	23.1	38.5	15.4	3.38	1
Inventory	7.7	7.7	15.4	23.1	46.2	0.0	3.17	2
Transport operations	15.4	23.1	30.8	7.7	23.1	0.0	2.36	3
Warehousing	7.7	30.8	46.2	15.4	0.0	0.0	1.83	4

Table 3 indicates the respondents' perceptions of the extent that BSc construction management undergraduate and (BSc) (Honours) academic programmes have enhanced logistics related site management skills in terms of percentage responses to a scale of 1 (minor) to 5 (major), and a MS ranging between 1.00 and 5.00. It is notable that only five (55.5%) out of the nine listed logistics related site management skills achieved MSs above the midpoint score of 3.00, which indicates that the respondents are of the opinion that construction management academic programmes enhance these five skills more to a major than a minor extent.

Yet again, it is notable that no MS is above 3.40. However, the MSs $> 2.60 \leq 3.40$ indicate that the respondents perceive that construction management academic programmes enhancement of the following skills can be deemed to be between some extent to a near major extent / a near major extent: delivery of material; material

storage; material ordering; material handling; movement of vehicles into and off site; removal of waste, and material sourcing. In addition, the MSs $> 1.80 \leq 2.60$ indicate that the respondents are of the opinion that construction management academic programmes' enhancement of material tracking and reverse logistics related skills can be deemed to be between minor to a near minor extent / a near minor extent.

Table 3. Extent to which academic programmes enhance logistics related site management skills

Skill	Response (%)						MS	Rank
	U	Minor.....Major						
		1	2	3	4	5		
Delivery of material (Just in Time)	0.0	15.4	0.0	30.8	38.5	15.4	3.38	1
Material storage	0.0	23.1	0.0	23.1	38.5	15.4	3.23	2
Material ordering	0.0	23.1	0.0	30.8	30.8	15.4	3.15	3
Material handling	0.0	23.1	7.7	23.1	30.8	15.4	3.08	4
Movement of vehicles into and off a site	0.0	15.4	15.4	38.5	7.7	23.1	3.08	5
Removal of waste (Construction & Demolition)	7.7	15.4	7.7	46.2	15.4	7.7	2.92	6
Material sourcing	0.0	23.1	23.1	30.8	15.4	7.7	2.62	7
Material tracking	7.7	23.1	15.4	53.8	0.0	0.0	2.33	8
Reverse logistics	38.5	30.8	7.7	23.1	0.0	0.0	1.88	9

Table 4 indicates the respondents' perceptions of the extent that BSc construction management undergraduate and BSc (Honours) academic programmes have contributed to an increase in students' understanding and appreciation of the functions and activities of site management relative to logistics in terms of percentage responses on a scale of 1 (minor) to 5 (major), and a MS ranging between 1.00 and 5.00. It is notable that all the listed functions / activities achieved MSs above the midpoint score of 3.00, which indicates that in general, the respondents are of the opinion that the contribution of construction management academic programmes to the understanding and appreciation of these functions / activities can be deemed to be more major than minor.

The MSs $> 3.40 \leq 4.20$ suggest that the respondents perceive that construction management academic programmes' contribution to increased understanding and appreciation of forecasting logistics requirements for a project, decision-making relative to construction logistics, evaluating and correcting logistics policies site management related functions can be deemed to be between a near major extent to a major extent / a major extent. In addition, the MSs $> 2.60 \leq 3.40$ indicate that the respondents are of the opinion that construction management academic programmes' contribution to increased understanding and appreciation of coordinating and organising construction logistics related functions can be deemed to be between some extent to a near major extent / a near major extent.

More importantly, it is notable that none of the MSs recorded in the survey achieved a score above 4.20, which indicates that in general there is a gap that must be bridged with respect to construction management undergraduate and honours academic programmes and construction logistics management.

Table 4. Extent to which academic programme contribute to improved understanding of logistics related functions

Function / Activity	Response (%)						MS	Rank
	U	Minor.....Major						
		1	2	3	4	5		
Forecasting logistics requirements for a project	0.0	7.7	0.0	15.4	53.8	23.1	3.85	1
Decision-making relative to construction logistics	0.0	7.7	0.0	30.8	53.8	7.7	3.54	2
Evaluating and correcting logistics policies	15.4	7.7	0.0	23.1	53.8	0.0	3.45	3
Coordinating construction logistics	7.7	15.4	7.7	30.8	30.8	7.7	3.08	4
Organising construction logistics	7.7	15.4	7.7	30.8	38.5	0.0	3.00	5

This argument is supported by the general comments incidental to the study. Such comments include:

“This area was not touched at all in honours or undergraduate”;

“Logistics should be lectured extensively just like quality management”;

“If possible a semester module should be dedicated to construction logistics and supply chain management”, and

“We did not do much of these parameters at university, however in our practical year we did.”

These findings perhaps explain why employing a logistics specialist is often undertaken during the execution of major projects such as the Heathrow Terminal 5 (T5) in the UK. Because firms in the construction industry generally do not train home-grown logistics managers, and also as logistics is gradually becoming a specialised and professional function, it can be argued that it seems possible that some knowledge of the discipline will soon form an important part of the training of a would-be construction or project manager (Sullivan *et al.*, 2010). The industry while generally perceived to be traditional in nature, is capable of making impressive leaps forward in some aspects of its logistics related performance in the same way it has managed to encourage improvement in culture and H&S in the past decade (Sullivan *et al.*, 2010). Although change in terms of logistics is much slower than expected, change is nevertheless a necessity that will take some time to be achieved (Ballard, 2010).

In other words, since construction / project managers and / or site agents may be the *de facto* in-charge of logistics on a traditional construction site, having necessary foundational knowledge of logistics can ensure that they are able to devote the required time and attention to logistics issues meaningfully. Many construction managers could enhance their professional practice by developing a good understanding of the basic functions and benefits of a systematic approach to logistics not only for large and complex projects, but also for smaller projects (Sullivan *et al.*, 2010). As indicated in Table 3, it can be inferred that reverse logistics related competency seems to be eluding students because this important area for the practice of construction management may have been under-explored by academics (Srivastava, 2008). In effect, processes

pertaining to the management of construction materials should be addressed so as to ensure increased cost / time savings and productivity since the CMR literature indicates that the process of delivering and handling construction materials are often so inefficient that they always lead to a significant amount of non-productive time on site (Ng *et al.*, 2009).

5 Conclusion and Recommendations

Clearly, there is a need to address the BSc and BSc (Honours) construction management academic programmes with respect to construction logistics in the South African university in order to meet the aspirations of students and the industry. The implications of the findings may also pertain to universities that have somewhat overlooked the need to include logistics management related course contents in their undergraduate and honours academic programmes. In particular, gaps relative to the inclusion of inventory, transport operations, warehousing and material handling topics in construction management academic programmes should be addressed.

Given that fresh university graduates are often assigned site management roles in South African construction and elsewhere in developing countries, it is imperative that construction management academic programmes provide a veritable platform for developing skills relative to material sourcing, ordering, delivery, tracking, storage, and handling. Specifically, the programme should attempt to improve students' knowledge areas that directly enhance their ability to use concepts of reverse logistics when they become active in the industry.

Though, the disseminated findings relate to a single university programme, it is here argued that given the importance of logistics in the construction process, construction management academic programmes in general should endeavour to address any logistics related noticeable gaps in their programmes. For example, as a direct result of the concise investigation undertaken in the South African university, a module titled "Logistics management in construction" has been included in the course curriculum of the construction management honours programme for the year 2011. Evaluation and improvement of built environment academic programmes thus have to be consistently undertaken so as to make sure universities will continue to meet the needs of the construction industry that is constantly changing.

Abstract:

Major international companies have established themselves in the United Arab Emirates (UAE) market by setting up their regional headquarters in Dubai. These international companies want to be in a growing market in a country where their companies are recognised and affiliated with a positive image. In addition, many companies have moved to the UAE for financial reasons as well. The UAE is an expanding regional market with the potential for future growth. However, there are cultural differences between Australia (and western countries generally) and the UAE (Middle Eastern). It is easy to have genuine and honest misunderstandings and, hence, it is simple to make innocent and sometimes mistakes. What those companies do not realise is that if they do not appropriately train and prepare their expatriates for their overseas assignments the expatriates are more likely to experience difficulties that can have a serious impact on their employees' effectiveness and on the company's activities.

This study considers project managers in the UAE, their experiences, their training and their needs and requirements. A survey of 100 Australian project managers based in the UAE was carried out to discover the dimensions of the cultural business environment.. The survey was followed by six case studies of senior management in large companies involved in project management, construction and property in the UAE. The results of these research investigations are summarised in this paper and recommendations on overcoming the deficiencies identified are discussed. Developing cross cultural training programs in line with the recommendations made in this research could lead companies to gaining a greater market share in the UAE and being recognised as an industry leader. Hence, investing in people is more likely to give the greatest return.

Keywords:

cross-cultural training, expatriates, investing in people, United Arab Emirates.

1 Introduction to Cross cultural training

In 1980 Hofstede carried out a study of top-ranking goals for professional technical personnel from a large variety of countries. In this study 'training' was ranked as number the one (1), priority (Luthans and Doh, 2009:74).

Mendenhall and Oddou (1985) as well as Stroh and Caligiuri (1998) have pointed out that for developmental and functional reasons successful expatriate assignments are invaluable to companies. This may explain why expatriate management literature has

paid a great deal of attention to the management of cross cultural adjustment of expatriates (Black and Gregerson, 1992). It is understandable that the expatriate management literature focuses on expatriate training and adjustment when so many expatriates fail. Expatriates are regarded as having failed in their overseas assignment if they return early from their assignment (Adler, 2001). There are also the non-financial effects of failure; things such as loss of business opportunities and damage to the company's reputation (Black and Gregersen, 1991; Naumann, 1993). Nevertheless, one should not forget that there are also psychological issues associated with failure; the expatriate most likely suffers lower self-confidence and damaged self-esteem (Mendenhall et al., 1985; Tung, 1987).

2 The Literature Review

Some researchers such as Shaffer and Harrison (1998) suggest that if the expatriate does not adjust to their life and to their international assignment satisfactorily they will be unable to function well and they almost certainly will return home or back to the parent company prematurely. Adjustment problems can be minimised through careful selection and training. Cross-cultural training as well as language training is especially important (Forster, 2000).

Stroh et al (1994) as well as Kramer et al (2001) support this argument by explaining that expatriates are more likely to complete their overseas assignment if they are prepared, which in return will lead to the expatriate being better adjusted to a foreign environment and more likely to successfully complete their overseas assignment. Mendenhall et al., (1985) categorized and introduced three (3) skills which are necessary for an expatriate to be successful in a cross cultural setting:

1. The self dimension
2. The relationship dimension
3. The perception dimension

2.1 Self Dimension

The self dimension refers to expatriate skills which enable him/her to be self effective in stress management, mental health and psychological well-being. Bandura (1977) also believed that expatriates need to believe that they are able to effectively deal with foreign surroundings. Mendenhall et al., (1985) add that expatriates need to be self-effective even when they may be experiencing uncertainty. A lot of researchers agree that people with high self-efficacy levels tend to be more persistent in learning and adopting new behaviors. Nicholson (1984) points out that those particular individuals adjust more quickly and are more successful in a foreign environment, because they are willing and are persistent to learn new behaviours.

2.2 Relationship dimension

The relationship dimension entails a variety of skills, which will enable an expatriate to be able to interact with ease with host nationals (Mendenhall et al, 1985). In addition, possessing relational skills can decrease the uncertainty related to an unfamiliar environment.

2.3 Perception dimension

The perception dimension constitutes a range of cognitive abilities, which help the expatriate evaluate the new unfamiliar environment. Mendenhall et al., (1985) believe that the greater the individual's perception skills the easier it is for them to understand the foreign culture and interpret it correctly. Additionally, perception skills help expatriates understand what is appropriate and what inappropriate behavior is and understand that it is of high significance when working in an environment such as the UAE.

However, even if expatriates have those three skills, in order to succeed in the UAE they will need to have suitable cross-cultural training. Cross-cultural training aims to assist expatriates enhance their knowledge and skills, which in turn will help the expatriate practice in an unfamiliar host country and to be more productive (Brewster and Pickard, 1994; Kealey and Protheroe, 1996; Harris and Brewster 1999).

According to Black and Mendenhall (1990) there is strong evidence that suggests that cross-cultural training is a critical factor in the preparation of expatriates on their overseas assignments. Tung (1979) suggests that the best and most effective cross-cultural training would have to be specific and should focus on a particular population and situation. For this reason it would be logical for Australian companies and organizations to provide their employees with specific cross-cultural training, which deals in detail with the UAE population and project management with reference back to Australian practice and attitudes.

This cross-cultural program would have to focus exclusively on the UAE culture, religion, and on how to practice project management in the UAE environment. This would have to cover laws in the UAE, leadership and ethics. Emiratis take business personally so it makes sense to learn as much as possible about the host country's culture in order to be able to avoid misunderstandings and conflict.

There are three phases of expatriate training; the pre-departure phase, on-site phase and the repatriation phase (Dunbar and Katcher, 1990). Many researchers in the area of cross culture agree that in order for expatriates to succeed in their overseas assignments they should have either pre-departure and/or on-site training (Warren and Adler, 1977; Tung, 1982; Black et al., 1990; Weaver, 1998; Gudykunst et al., 1996; Ferraro, 1998; Caligiuri et al, 2001).

3 Research Methodology

This research commenced with an extensive literature review on cross-cultural training. The literature review led the author to believe that there is a lack of cross-cultural training provided to Australian expatriates who are working, or are about to commence work in the UAE. To analyse this proposition the authors designed an online survey, which was distributed to human resources managers and project managers already working in the UAE.

Once the online survey was analysed it indicated that there was a lack of cross-cultural training provided to those expatriates. To gain a better picture as to why this was the case and to find out what could be done to help expatriates the authors decided to

conduct six in-depth case studies to better understand expatriates and their training needs.

All six case studies are based on Australian companies that have spread internationally including to the UAE. The reason for choosing Australian companies was that this research focused on Australian project managers working and living in the UAE, and was limited to this defined population.

Once all the information from the case studies was collected, analysis of the case studies revealed that although the UAE had a large expatriate population of about 80 per cent, most expatriates live in segregated communities. In addition, the case study results confirmed the earlier survey; Australian expatriates were lacking cross-cultural training. The results and recommendations will be discussed in detail in the next section.

4 Results

Most respondents did not receive any cross-cultural training and the ones that received some type of assignment preparation claimed that it was not adequate. More importantly the case studies enabled the authors to make recommendations on what type of cross-cultural training should be offered, how it should be delivered and when it should be delivered to the expatriates for the best effect.

4.1 Expatriate preparation

The majority of the large expatriate population tend to congregate with people with a similar language and culture. For instance, Australians have their social private clubs, luxury beach clubs, sports clubs, bars and this is where they socialise with other Australians. Executive expatriates live in villas with pools, and they send their children to private schools, whereas the low paid manual workers, who are usually from India, Pakistan and the Philippines, live in bleak workers' compounds. The type of employment and salary levels ensures everyone moves in their own circles. Nevertheless, both well paid and low paid workers still need to adjust to an unfamiliar environment.

After analysing the relationships between host nationals and expatriates, Caligiuri (2002) reported that greater interaction with host nationals positively relates to cross-cultural adjustment. However, as demonstrated in Hofstede's (2003) findings the Arab World is very different to Australia. This indicates that interaction with host nationals could be challenging.

Hofstede (2003) points out that with an *uncertainty avoidance* (UAI) of 68 out of 100 and great *power distance* (PDI) of 80 out of 100, are the predominant characteristics for the Arab region. This indicates that it is anticipated that traditional leaders separate themselves from the group and issue complete and specific directives. This is due to the fact that these societies are more likely to pursue a caste or a class system that does not permit significant upward mobility of its people. They are also highly rule-oriented with laws, rules, regulations and controls in order to diminish the amount of uncertainty, while discrimination of power and wealth have been allowed to grow within the society. If one were to combine those two dimensions a situation would arise where the people on the top (the leaders) would have ultimate authority and power.

Additionally, a high PDI ranking suggests a high level of inequality of power and wealth within the society. This society has a belief that leaders will separate themselves from the group and this condition is accepted by the society as their cultural heritage. For example, Australia is relatively low in this dimension, with an index of 36, compared to the world average of 55. This is indicative of a greater equality between societal levels.

The high UAI ranking indicates that the Arab society has a low level of tolerance for uncertainty. In an effort to minimize or reduce this level of uncertainty, strict rules, laws, policies and regulations have to be, and usually are adopted and implemented. If those rules and regulations are strictly implemented and followed by the society, those people can successfully avoid and/or eliminate the unexpected. As a result most people from this region do not willingly accept change and are extremely risk adverse.

The third highest Hofstede Dimension in Arab countries is the *masculinity index* (MAS), with a ranking of 52 out of 100. This rank is about average on Hofstede's dimensions, which can be explained by the fact that when it comes to decision making people from the Arab World are more caring (feminine) than people with western values.

The lowest Hofstede Dimension for the Arab World is the *individualism* (IDV) ranking at 38 out of 100. The world average ranking for this dimension is 64. This translates into a collectivist society (the Arab World) as compared to individualist culture (Australia) and is apparent in a close long-term commitment to group and family. In a collectivist society loyalty is paramount and overrules most other societal rules.

Australia is the complete opposite when it comes to the IDV dimension. Hofstede's research indicates that Australia has very high levels of individuality. In fact, Hofstede scored Australia as 90 out of 100, the second highest score of any country in Hofstede's survey, the United States being the highest with a ranking of 91.

It is obvious from Hofstede's Dimensions that Australia and the UAE are very different. If expatriates are not prepared and do not attempt to learn and know about the different cultural, social, religious, legal and business rules they can easily fail and be unsuccessful.

It has become increasingly apparent that cross-cultural training is important in preparing expatriates for their overseas assignments. This training has long been advocated as a means of facilitating effective cross-cultural interaction between the expatriate and the host nationals. In the case where expatriates do not get cross-cultural training or inadequate training they could "*fail*" in their international assignment. An expatriate is considered to have failed if that individual has not completed the international assignment and if he/she needs to be replaced with a new expatriate. Expatriate failure does not only cause damage to the company, but it can also cause the expatriate to lose his/her job, limit future career prospects and encourage low self-esteem. In order to eliminate expatriate turnover this research has focused on cross-cultural training and preparation of Australian expatriate project managers working in the UAE.

4.2 Business and Arabic characteristics

Aside from meeting the challenges of new job responsibilities, Australian project managers also have to adjust to a new and unfamiliar social and business climate as well as a new culture. In this research adjustment has referred to the process of the expatriate's ability to fit-in, so that he or she can feel comfortable and at ease with the new surroundings. As discussed earlier, there are many reasons for expatriates to return home prematurely. Some of those issues can be dealt with if appropriate and adequate cross-cultural training is provided. *Culture shock*, for example, can be minimised if the expatriates are prepared for what to expect and the culture shock can last for a shorter time period when compared to the situation if the expatriate did not get any preparation. The faster the expatriate gets over the culture shock and adjusts, the faster that individual can work at full capacity.

Certain Arabic characteristics need to be studied and expatriates need to appropriately prepare before starting to do business in the UAE. The circular approach to meetings and debate, polychronic time management activities and timing, the emphasis on hospitality, the importance of networking and the preference for making use of contacts, should be learned, understood, appreciated and followed.

4.3 Time and Timing

The Arabs respect westerners who come on time to meetings even if they themselves are late. However, to Arabs time is not as important as to the westerners. In the Arab world there is more emphasis on harmony. This means that in order to maintain harmony being late to meetings, delays and interruptions during meetings are common and are tolerated.

However, the locals do recognise that delays, lateness, interruptions and that time is an unlimited resource can cost them money and perhaps lose them business deals with outsiders. Nevertheless, being time conscious and on time is hard for the Arabs as they cannot do that at the expense of personal relationships. In addition, Arabs are classified as being "*polychronic*" (multi-time) as opposed to most westerners who are "*monochronic*" (single-time). This means that the Arabs will have several meetings at the same time, and expatriates need to get used to constant interruptions during meetings.

Arabs put more emphasis on "*Timing*" than "*Time*". Timing cannot be managed as it is sensed. Timing is all about how the parties get along, the mood of the meeting, and trust that must be established in previous visits. This is one more reason why it takes a lot of meetings and a long time to reach an agreement on an issue.

However, in some cases keeping someone waiting is used to demonstrate power, just like delays on a contract or a project can be a power tactic or a test of character. Expatriates need to learn to be flexible, patient and persistent when they want something done. Additionally, when expatriates are working out a project timeline it needs to be stressed that being conservative will work in the expatriate's favour and building in a big margin for error is equally important.

4.4 Risk and Decision Making

Most of the UAE, with the exception of Dubai, is very risk averse. Hence, this is why most company headquarters are in Dubai. The Kingdom continues to be the major force governing all aspects of the economy by having a high degree of regulation governing all areas of life and business. The UAE overall is reluctant to accept rapid change.

In the UAE the leader, or the Sheik, is seen as the “*father figure*” and that is also how he leads, his decisions are final and are rarely ever questioned. The “*father*” has the absolute power for his decisions and his vision and approach rules and dictates the success and failure of the group. He expects absolute loyalty and any type of criticism is rarely tolerated.

The patriarchal nature of the Arab society means that the delegation of power is rare and precarious for those on the receiving end. In the UAE decision making, power and wealth are concentrated in the hands of a few and they do not like to share it around. This is very obvious when it comes to labour laws and employment contracts, which usually favour the employer and the employees generally have no rights. Despite significant improvements there are still a lot of issues and the *International Human Rights Watch* has hundreds of cases reported every week.

Most of the labourers and contractors in the UAE are immigrant workers and foreign investors and business contracts leave them exposed, since they give power to the clients (usually an Emirati company).

4.5 Communications

Expatriates working in the UAE come from all over the world. This is why the language of most business is English. It is important, however, to learn some Arabic and master some basic Arabic phrases and expressions; this would be very much appreciated by the Arabs. Learning Arabic numbers the way that are written and spoken would also help expatriates to understand numbers/prices when negotiations are done in Arabic; it is also helpful for the basic task of getting around the city and in office buildings.

In some meetings there are people that do not speak English. In that case a fully accredited translator can be provided by the local chamber of commerce and should be used. Even when a translator is being used it is important to check that both parties understand what is happening. In cross cultural dealings ‘it is not what you said, but what they have heard’. In a foreign country one needs to listen with the ears, eyes and the heart. This means that paying attention to body language is very important in a society such as the UAE. Body language, such as gestures have hidden meanings. Since the Arabs are high context communicators there is a lot of broader meaning to the words that they use. For this reason body language and the mood of the meeting needs to be taken into consideration, not only what has been said. An example would be the word “*Inshallah*” (God willing) when an Arab says “*Inshallah*” it could mean a vast number of things, such as “*Yes*”, “*No*”, “*Maybe*”, “*Someday*”, or “*Never*”.

Additionally, Arabs do not place much emphasis on written communications as they are a highly verbal society. This can work in the expatriates favour as in face to face meetings the full meaning of what is said versus body language (e.g., eye contact, gestures, facial expressions, etc.) can be observed and at the same time it can be checked for mutual understanding. It is important to become an active listener.

This means that when it comes to communication (unlike the west that prefers written communication) the Arabs prefer personal visits, which have the biggest impact, or phone calls when visits are not possible and these have more impact than a series of emails. Emails often get ignored, overlooked or take very long time to be replied to.

Arabs are hospitable and place a great deal of emphasis on outward expressions, and the Emiratis are no different. They love to entertain and this is also a great way to form a bond with the Emiratis. This is why invitations need to be accepted graciously and expatriates should learn appropriate etiquette before attending the event. Once there is a bond established with the Emirati and an expatriate they consider the expatriate as a friend and business dealings can commence.

4.6 Relationships

The Arabs put a big emphasis on relationships and a reliance on absolute trust when they are doing business. This is the basis for doing business in the UAE and this too explains why they do not like to use formal written contracts.

In the UAE it is all about building and maintaining relationships. Once a relationship is established it needs to be nurtured with frequent visits. Business is highly personal and relationships affect everything from negotiations, getting approvals, cutting the red tape, getting things done fast, as well as recruiting and hiring. More than anywhere else preparation is of the highest importance before starting to build relationships in the UAE.

4.7 Training and Learning

Generally research on training has been limited to the U.S., and it is not always applicable to other countries. Therefore, this research has specifically focused on the UAE and Australia. This research has discovered that cross-cultural training facilitates faster adjustment of Australian project managers in the UAE and contributes to their success.

All six case studies agree that, “*yes, cross-cultural training is important*”. However, the training that was provided only touched on culture, customs and business. It did not go into enough depth to be helpful. It was more informative than helpful. Additionally, the training which was provided was not specific. It only gave the expatriates brief and superficial information about the UAE.

In addition, all six case studies agree that on-site departure training is important, but the six case studies also revealed that the training was non-existent, incomplete or insufficient. In fact, the online survey revealed that 76% of respondents did not receive pre-departure training. Additionally, 61.4% of respondents reported that even when they were on-site they did not receive any training. This means that 61.4% of participants did not receive any training at all. Cross-cultural training is vital to the success of expatriates overseas and it should not be ignored by human resource managers and executives. As indicated by the respondents, not providing effective, up-to-date and efficient cross-cultural training could have devastating professional and personal consequences for both the expatriates and their companies.

Many researchers have conducted extensive studies which indicate that there is a positive relationship between cross-cultural training and the expatriate’s ability to faster

adapt to the new environment (Black et al., 1990, 1992; Naumann, 1993). In fact, cross-cultural training is critical for expatriates who do not know the host nation's culture, work ethics and social etiquette. Cross-cultural training can help those individuals not only to adjust faster to the new country, but also to be more efficient, effective and successful in their overseas assignment. Through cross-cultural training expatriates gain a better understanding and more knowledge about the host country and this in return enhances their self-efficacy; it reduces their anxiety levels and allows them to absorb culture shock. It thereby gives them an advantage over someone with no cross-cultural training, because the trained expatriates are familiar with the host country and this facilitates faster cross-cultural adjustment.

The training should include pre-departure training, on-site training and repetition training where every few months a refresher training workshop is offered. Training offers numerous advantages to the expatriate, by helping expatriates deal with culture shock and unexpected events better and it also lessens the uncertainty of interactions with host nationals. It is understandable that companies struggle to develop an appropriate mental frame of reference for their expatriates for dealing with unfamiliar cultures. However, they need to rectify this as expatriates need a frame of reference in the form of cross-cultural training and mentors.
